Chapter Thirty-seven

PAVEMENT DESIGN

37-1 GENERAL

37-1.01 Pavement Design Definitions

1. Average Daily Traffic (ADT). The total volume during a given time period (in whole days), greater than one day and less than one year, divided by the number of days in that time period.
2. Base Course. The layer used in a pavement system to reinforce and protect the subgrade or subbase.
3. Binder. The asphalt cement used in HMA pavements specified according to the Superpave Performance Graded system.
4. Class I Roads and Streets. Facilities with 4 or more lanes and one-way streets with a structural design traffic greater than 3500 ADT.
5. Class II Roads and Streets. Two or three lane streets with structural design traffic greater than 2000 ADT and all one-way streets with a structural design traffic less than 3500 ADT.
6. Class III Roads and Streets. Roads and streets with structural design traffic between 400 and 2000 ADT.
7. Class IV Roads and Streets. Roads and streets with structural design traffic less than 400 ADT.
8. Composite Pavement. A pavement structure consisting of HMA surface course overlaying a PCC slab of relatively high bending resistance which serves as the principle load-distributing component.
9. Continuously Reinforced Concrete Pavement. A rigid pavement structure having continuous longitudinal reinforcement achieved by overlapping the longitudinal steel reinforcement.
10. Conventional Flexible Pavement. A flexible pavement structure consisting of a HMA surface course and a combination of aggregate base, and granular subbase or modified soil layers.
11. Design E_{RI} . Resilient modulus is the repeated deviator stress divided by the recoverable (resilient) strain. For the fine-grained subgrade soils that predominate in Illinois, E_{RI} is the resilient modulus for a repeated deviator-stress of approximately 6 ksi.

BUREAU OF LOCAL ROADS & STREETS

37-1(2)

PAVEMENT DESIGN

Jan 2006

-
12. Design Lane. The traffic lane carrying the greatest number of single and multiple vehicular units.
 13. Design Period (DP). The number of years that a pavement is to carry a specific traffic volume and retain a minimum level of service.
 14. Equivalent Single Axle Loads (ESAL's). A numeric factor that expresses the relationship of a given axle load in terms of an 18 kip single axle load.
 15. Extended Lane. A monolithic paved lane, typically 2 ft wider than the marked pavement riding surface, used to reduce PCC pavement edge stresses. Lanes built with integral curb and gutter may be considered extended lanes and designed as such.
 16. Heavy Commercial Vehicles (HCV's). The combination of single and multiple unit vehicles (SU's + MU's). These typically account for the majority of the 18 kip ESAL applications to the design lane anticipated during the design period.
 17. HMA Design Mixture Temperature. Design temperature of HMA mixture in the pavement based on its geographical location.
 18. HMA Design Modulus (E_{AC}). The HMA mixture modulus (E_{AC}) in the pavement corresponding to the "HMA Design Mixture Temperature".
 19. HMA Design Strain. HMA design tensile strain at the bottom of the HMA pavement layer.
 20. Hot Mix Asphalt (HMA). A mixture consisting of coarse and fine mineral aggregate uniformly coated with asphalt binder. Used as a base, surface, or binder course.
 21. Immediate Bearing Value (IBV). A measure of the support provided by the roadbed soils or by unbound granular materials. The field IBV is obtained from the Dynamic Cone Penetrometer (DCP) test, or in the lab from a penetration test (according to AASHTO T193) on a 4 in diameter, molded sample, immediately after compaction.
 22. Integral Curb and Gutter. A curb and gutter that is paved monolithically with the pavement. Used to reduce edge stresses and provide a means of surface drainage.
 23. Modified Soil Layer. A subgrade soil layer treated with a modifier such as lime, fly ash, Portland cement, or slag-modified cement, and constructed according to the BDE Special Provision for Soil Modification.
 24. Multiple Units (MU). Truck tractor semi-trailers, full trailer combination vehicles, and other combinations of a similar nature.
 25. Overloads. Loads that are anticipated to exceed the load limits from which the design TF's were developed. Typically, overloads are created from commercial, garbage, construction, and farm trucks; permit loads; buses; and some farm implements.

BUREAU OF LOCAL ROADS & STREETS

Jan 2006

PAVEMENT DESIGN

37-1(3)

26. Passenger Vehicles (PV). Automobiles, pickup trucks, vans, and other similar two-axle, four-tire vehicles.
27. Pavement Structure. The combination of subbase, base course, and surface course placed on a subgrade to support the traffic loads and distribute the load to the roadbed.
28. Random Joints. Transverse joint spacing that is randomized to prevent resonant responses in vehicles. Designers must request a written variance from Central BLRS in order to use randomized transverse joint spacing.
29. Reliability. The reliability of a pavement design-performance process is the probability that a pavement section designed using the process will perform satisfactorily for the anticipated traffic and environmental conditions for the design period. The following factors may impact the design reliability: materials; subgrade; traffic prediction accuracy; construction methods; and environmental uncertainties.
30. Single Units (SU). Trucks and buses having either 2 axles with 6 tires or 3 axles.
31. Skewed Joints. Transverse joints that are not constructed perpendicular to the centerline of pavement. The use of skewed joints is not encouraged.
32. Stage Construction. The planned construction of the flexible pavement structure in 2 or more phases. A time period of up to 2 years may elapse between the completion of the first stage and the scheduled construction date of the final stage.
33. Structural Design Traffic. The ADT estimated for the year representing one-half the design period from the year of construction.
34. Subbase. The layer used in the pavement system between the subgrade and the base course.
35. Subgrade. The prepared and compacted soil immediately below the pavement system and extending to a depth that will affect the structural design.
36. Subgrade Support Rating. Rating of subgrade support used in full-depth HMA, rigid, and composite pavement designs. There are three ratings — poor, fair, and granular. These ratings are based on the silt, sand, and clay contents of the subgrade.
37. Surface Course. One or more layers of a pavement structure designed to accommodate the traffic load, the top layer of which resists skidding, traffic abrasion, and the disintegrating effects of climate. This layer is sometimes called the wearing course.
38. Three Times Nominal Maximum Aggregate Size.

BUREAU OF LOCAL ROADS & STREETS

37-1(4)

PAVEMENT DESIGN

Jan 2006

39. Tied Curb and Gutter. A PCC curb and gutter that is tied with reinforcing steel to the pavement so that some of the pavement load is transferred to the curb and gutter. Used to reduce pavement edge stresses and provide a means of surface drainage. In order to be considered a tied curb and gutter and to receive a pavement thickness adjustment for tied curb and gutter, use a No. 6 or larger reinforcement bar to tie the pavement to the curb and gutter.
40. Tied Shoulder. A PCC stabilized shoulder tied with reinforcing steel to the pavement so that some of the pavement load is transferred to the shoulder. Used to reduce pavement edge stresses. In order to be considered a tied shoulder and to receive the pavement thickness adjustment for tied shoulders, use a No. 6 or larger reinforcement bars to tie the pavement to the PCC shoulder.
41. Traffic Factor (TF). The total number of 18 kip equivalent, single-axle, load applications to the design lane anticipated during the design period, expressed in millions.
42. Untied Shoulder. Any shoulder that does not provide edge support. The shoulder may consist of earth, aggregate, or bituminous stabilized materials. PCC shoulders that are tied with No. 5 or smaller reinforcing steel are considered untied for purposes of determining pavement thickness.

37-1.02 Minimum HMA Lift Thickness

All HMA surface, binder, and leveling binder lifts must comply with the lift thicknesses in Figure 37-1A.

Mixture Superpave	Typical Use ⁽¹⁾	Leveling Course Minimum Lift Thickness ⁽²⁾⁽³⁾ , in (mm)	Surface/Binder Course Minimum Lift Thickness ⁽²⁾ , in (mm)
IL-4.75	B/L	3/8 (10)	3/4 (19)
IL-9.5	S/B/L	3/4 (19) ⁽⁵⁾	1 1/8 (29)
IL-12.5	S/B/L	1 1/4 (32)	1 1/2 (38)
IL-19.0 ⁽⁴⁾	B/L	1 3/4 (44)	2 1/4 (57)
IL-25.0 ⁽⁴⁾	B	Not Allowed	3 (76)

- Notes:
1. S = Surface; B = Binder; L = Leveling Binder
 2. Minimum thicknesses are the nominal thickness of the lift.
 3. If the leveling course is placed at or above the minimum thickness specified for surface/binder course, density will be required.
 4. This mix may not be used as a surface lift.
 5. If the IL-9.5mm leveling binder is being placed over crack and joint sealant, the minimum lift thickness may be 1/2 in (13 mm).

HMA SURFACE, BINDER, AND LEVELING BINDER LIFT THICKNESSES**Figure 37-1A**

37-1.03 Skid Resistance on HMA Surface Courses

Aggregates with suitable friction shall be specified for all HMA surface courses on federal-aid projects and local projects on the state letting. Figure 37-1B lists four surface course mixtures that have been developed to provide adequate skid resistance for various Average Daily Traffic (ADT) levels and number of lanes.

Number of Lanes	Frictional Requirements (ADT)			
	Mixture C	Mixture D	Mixture E	Mixture F
≤ 2	≤ 5,000	> 5,000	N/A	N/A
4	≤ 5,000	5,001 to 25,000	25,001 to 100,000	> 100,000
≥ 6	N/A	5,001 to 60,000	60,001 to 100,000	> 100,000

Note: ADT levels are for the expected year of construction.

FRICTIONAL REQUIREMENTS FOR SURFACE MIXES

Figure 37-1B

Designers should consider using the appropriate friction aggregate on projects funded by other sources and on a local letting

37-1.04 Selection of Pavement Type

The local agency must specify pavement type on the design plans; however, for MFT funded projects, “alternative” or “type” bids may be used according to Section 12-1.03. Figure 37-1C provides a decision tree flow chart as a guide for the design of pavements.

The 1993 *AASHTO Guide for Design of Pavement Structures* lists a number of principal and secondary factors that may play a role in the pavement selection process. Some of these include the following:

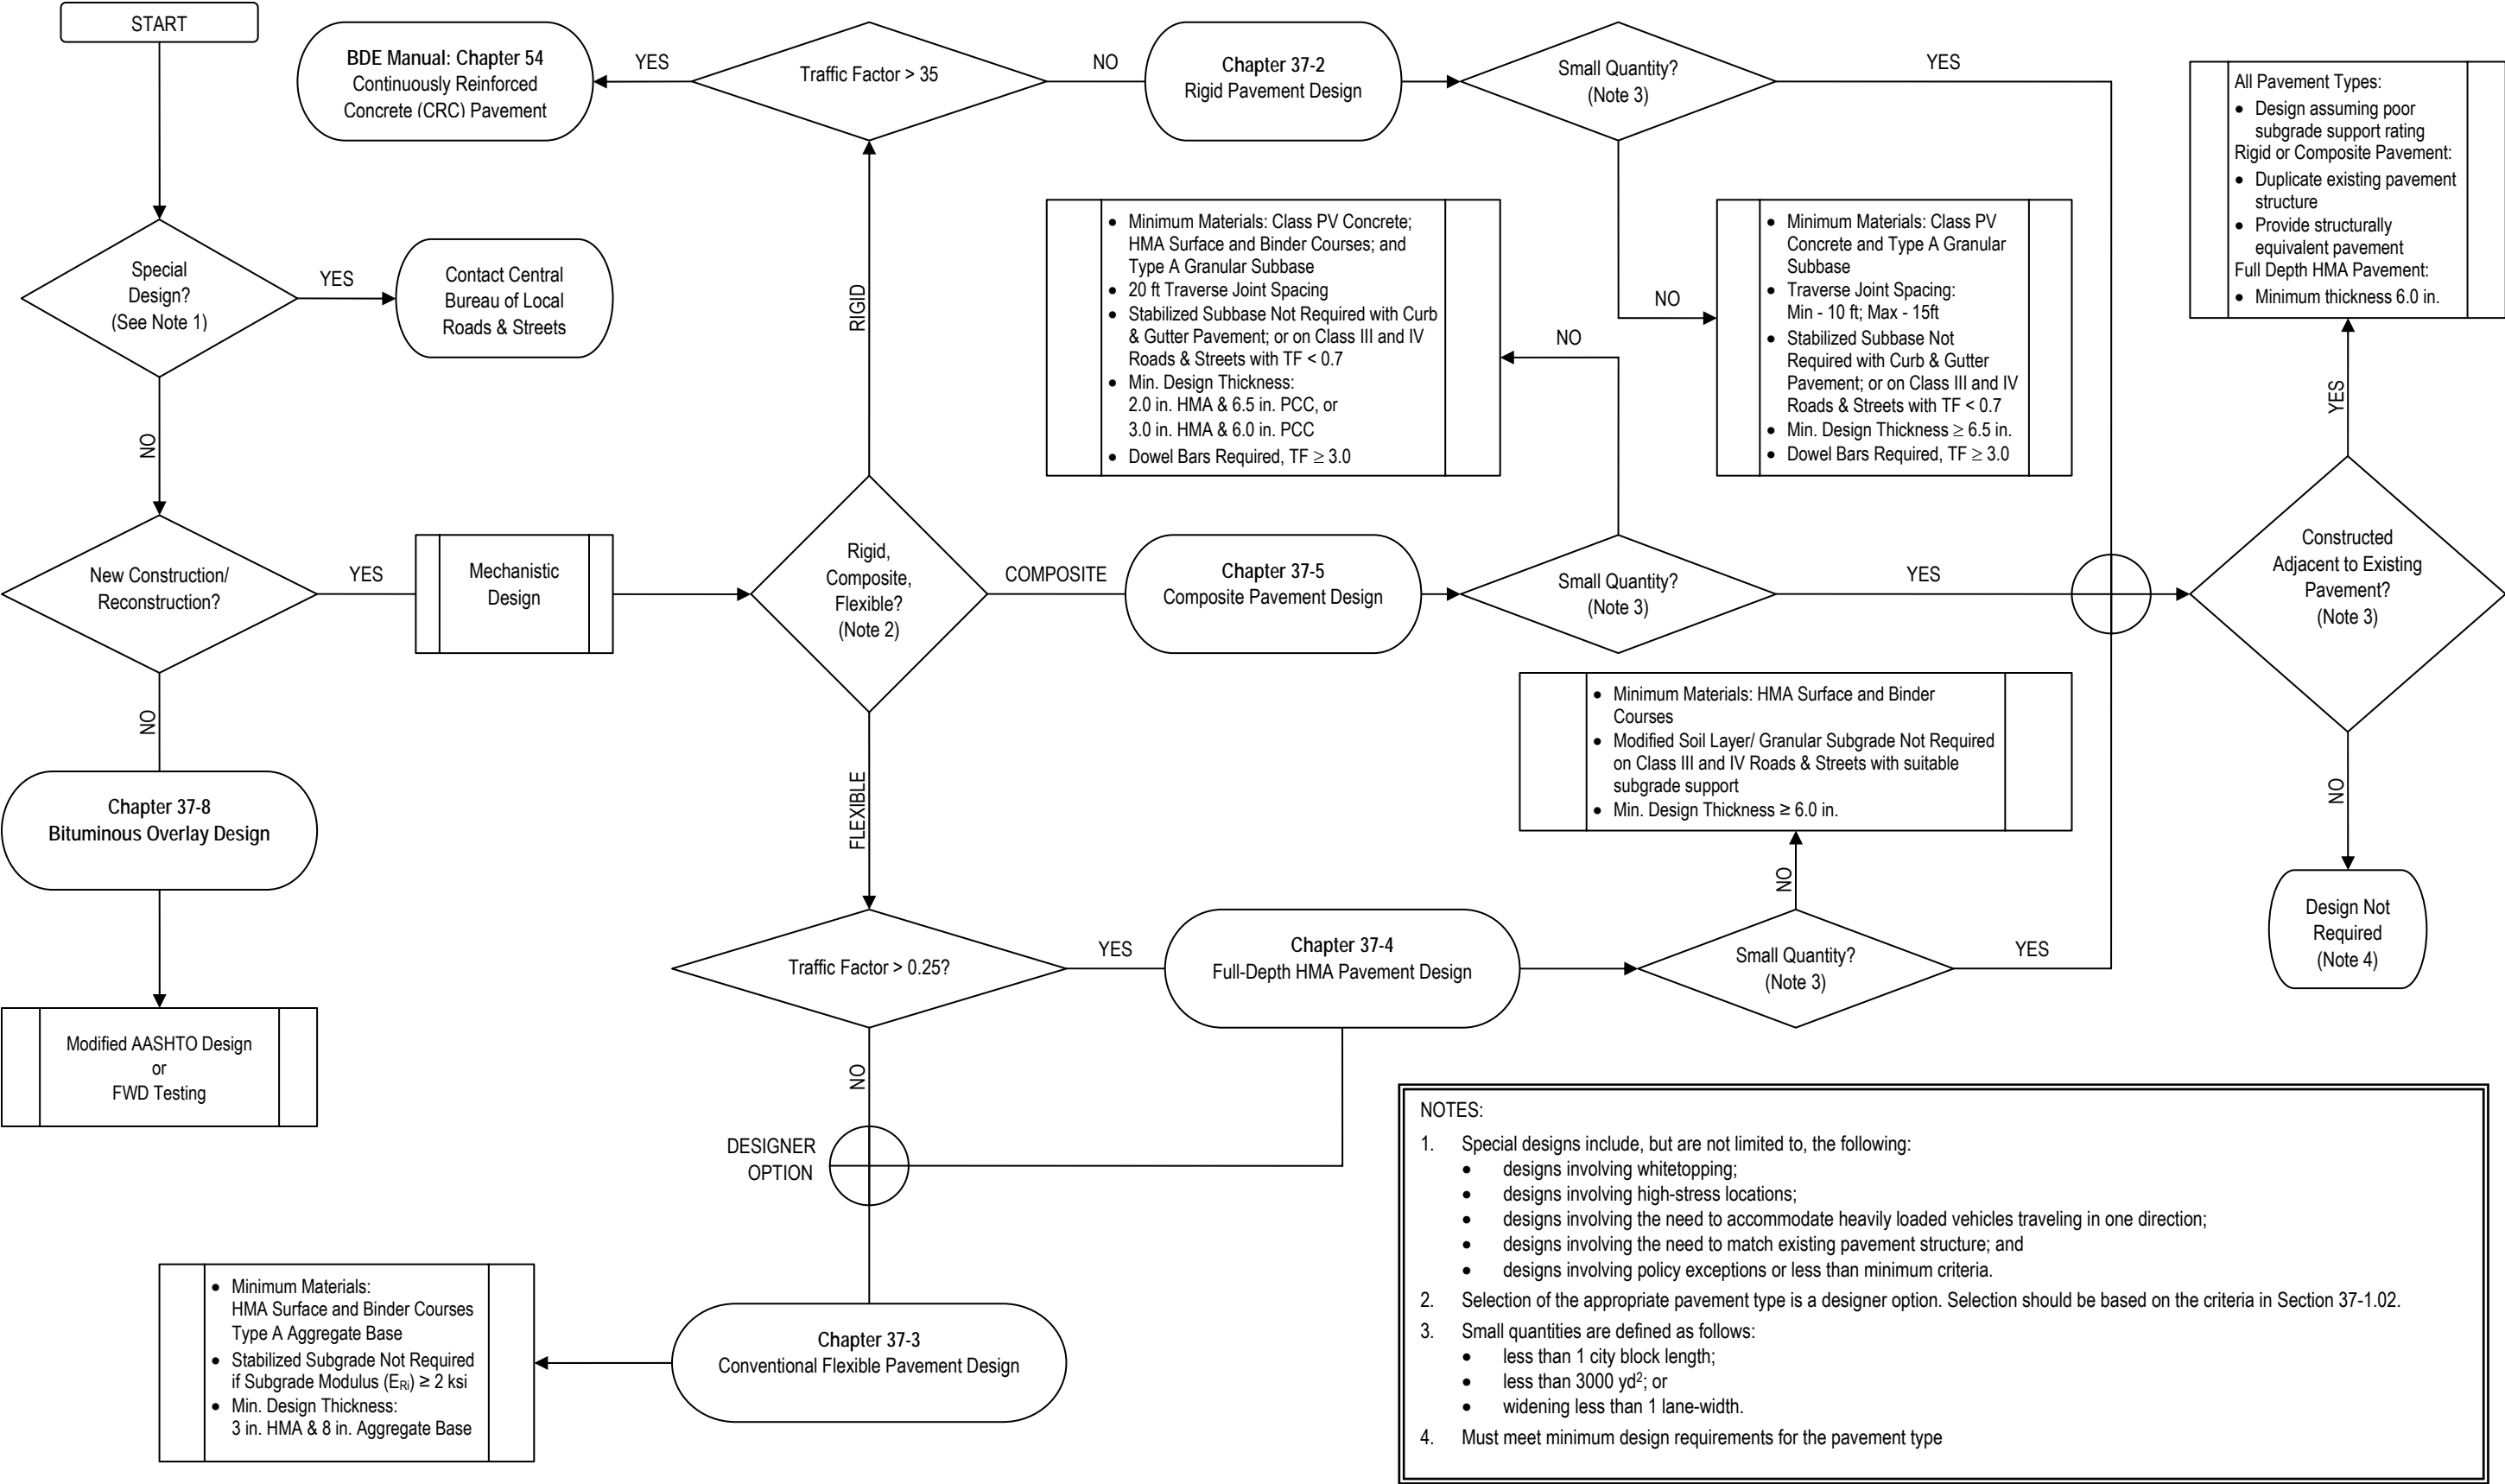

1. Principal Factors. These include traffic, soil characteristics, weather, construction considerations, recycling, and cost comparison.

BUREAU OF LOCAL ROADS & STREETS
PAVEMENT DESIGN

37-1(6)

Jan 2006

2. Secondary Factors. Secondary factors may include performance of similar pavement in the area, adjacent existing pavements, conservation of materials and energy, availability of local materials or contractor capabilities, traffic safety, incorporation of experimental features, stimulation of competition, and local agency preference.

FLOWCHART FOR SELECTION OF DESIGN METHODOLOGY, PAVEMENT TYPE, AND DESIGN CRITERIA

Figure 37-1C

37-2 RIGID PAVEMENT DESIGN FOR LOCAL AGENCIES

37-2.01 Introduction

37-2.01(a) Types of Rigid Pavements

Rigid pavement is a pavement structure whose surface and principal load-distributing component is a Portland cement concrete (PCC) slab of relatively high-bending resistance. The two types of rigid pavements are as follows:

1. Non-Reinforced Jointed. Jointed pavement without steel reinforcement that may or may not use mechanical load transfer devices (e.g., dowel bars).
2. Continuously Reinforced. Pavement with continuous longitudinal steel reinforcement and no joints. It is typically used on high-volume Class I roads (e.g., Interstate routes and freeways).

The non-reinforced jointed pavement design procedure is discussed in this Section. Chapter 54 of the *BDE Manual* provides the design procedures for continuously reinforced concrete pavements.

37-2.01(b) Usage of Procedure

Use the pavement design procedures provided in Section 37-2 for all local road and street projects where a rigid pavement is desired. If the local agency intends to transfer jurisdiction following pavement construction, both agencies involved in the jurisdictional transfer should agree on the design.

A pavement design is not required when small quantities of pavement are to be constructed. Small quantities are defined as follows:

- less than 1 city block in length,
- less than 3000 yd², or
- widening less than 1 lane-width.

Where small quantities are to be constructed adjacent to an existing pavement, the designer should:

- duplicate the existing total pavement structure,
- provide a structurally equivalent pavement, or
- design assuming a poor subgrade support rating.

BUREAU OF LOCAL ROADS & STREETS

37-2(2)

PAVEMENT DESIGN

Jan 2006

37-2.02 Basic Design Elements**37-2.02(a) Minimum Material Requirements**

The minimum requirement for Portland cement concrete is Class PV concrete, as specified in the *IDOT Standard Specifications*. Use Type A granular subbase, according to the *IDOT Standard Specifications*, where granular subbase is specified.

37-2.02(b) Class of Roads or Streets

The class of the road or street for which the pavement structural design is being determined is dependent upon the structural design traffic. These road classifications are defined in Section 37-1.

37-2.02(c) Design Period

The design period (DP) is the length of time in years that the pavement is being designed to serve the structural design traffic. For all classes of rigid pavements, the minimum design period is 20 years.

37-2.02(d) Structural Design Traffic

The structural design traffic is the estimated ADT for the year representing one-half of the design period. For example, when the design period is 20 years, the structural design traffic will be an estimate of the ADT projected to 10 years after the construction date.

The structural design traffic is estimated from current traffic count data obtained either by manual counts or from traffic maps published by IDOT. If SU and MU counts are not available for Class III and IV roads and streets, an estimate of those counts may be made from the component percentages of the total traffic in Figure 37-2A.

Class of Road or Street	Percentage of Structural Design Traffic		
	PV (%)	SU (%)	MU (%)
III	88	7	5
IV	88	9	3

**TRAFFIC PERCENTAGE
(Class III and IV)**

Figure 37-2A

37-2.02(e) Traffic Factors

For Class I, II, and III roads and streets, the design Traffic Factor (TF) for rigid pavements is determined from the 73,280 lb and 80,000 lb load limit formulas shown in Figures 37-2B and 37-2C. The formulas are based on the state wide average distribution of vehicle types and axle loadings, which are directly applicable to most roads and streets. However, cases will arise in which a formula cannot be used, and a special analysis will be necessary (e.g. a highway adjacent to an industrial site with heavy commercial vehicles (HCV's) entering and leaving the site generally traveling empty in one direction and fully loaded in the other). These cases should be referred to the Central BLRS for special analysis. The local agency must provide the Central BLRS with the structural design traffic; the design period; traffic distribution by PV, SU, and MU; and loading distribution of HCV traffic.

The TF equations in Figure 37-2C are provided to accommodate 80,000 lb trucks. In Illinois these larger and heavier trucks are permitted to use the Interstate system and a system of designated State routes. In addition, trucks operating on this system are allowed to have limited access to points of loading and unloading and facilities for food, fuel, repairs, and rest. Local authorities of roads and streets also have the authority to designate 80,000 lb truck routes. The pavement design procedure for 73,280 lb and 80,000 lb routes is the same except for the TF equations.

For Class IV rigid pavements, thicknesses are provided in Section 37-2.03(b) based on the daily volume of HCV's; therefore, a design TF is not necessary.

For TF greater than 10.0, the designer should follow the rigid pavement mechanistic design procedure outlined in Chapter 54 of the *IDOT BDE Manual*. Contact the Central BLRS for additional information.

37-2.02(f) Transverse Pavement Joints

For Class I, II, and III pavements, thickness design curves are given for transverse joint spacings of 12.5 ft and 15 ft (Figures 37-2D and 37-2E). Pavement thickness for each of these joint spacings can be determined through the pavement design procedure. Then the designer can determine the desired combination of transverse joint spacing and pavement slab thickness. The maximum recommended transverse joint spacing for jointed PCC pavements are given in Figure 37-2F.

Joint spacings in excess of 15 ft or less than 10 ft require a design variance from the Central BLRS. The Central BLRS will provide the thickness designs for pavements granted for these variances.

Slab Thickness (in)	Maximum Transverse Joint Spacing (ft)
< 8.0	12.5*
≥ 8.0	15.0

** Appropriate for all Class IV pavements.*

MAXIMUM TRANSVERSE JOINT SPACING

Figure 37-2F

A number of factors must be carefully considered when selecting transverse joint spacing. Longer joint spacing will result in higher curling and warping stresses, which when combined with load stresses could promote premature failure by fatigue. Longer joint spacing will also result in greater joint movement, which may result in increased joint distress. In urban areas where there is a higher concentration of pavement discontinuities (e.g., manholes, storm sewer outlets, traffic detector loops), longer joint spacing can be less forgiving, leading to cracking between joints. However, shorter joint spacing can result in unstable slabs that may rock and pump under repeated loadings. Shorter joint spacing also results in more joints, thereby increasing the expense of joint maintenance over the life of the pavement. In no case is a slab length less than 6 ft recommended.

The volume of traffic the pavement will carry determines the type of load transfer device necessary to control faulting at the joints. Mechanical load transfer devices (e.g., dowel bars) are required on pavements that have a design TF of 3.0 or greater. For pavements with a TF less than 3.0, the designer has the option of using dowel bars or relying on aggregate interlock for load transfer. Shorter joint spacing is recommended when dowel bars are not used.

Designers desiring use of a randomized transverse joint spacing must request a written variance from the Central BLRS. The maximum transverse joint spacing allowed will be 15 ft.

The use of skewed transverse joints is not encouraged. Failure of the portion of the slab where the skewed joint forms an acute angle with the longitudinal joint has been a common occurrence nationwide, and has proven a difficult failure to patch and maintain. Designers desiring use of skewed joints must request a written variance from the Central BLRS.

37-2.02(g) Longitudinal Pavement Joints

Longitudinal joints run parallel to the pavement length and serve the dual function of separating the pavement into travel lanes and controlling longitudinal cracking. Longitudinal joints may be formed by sawing the slab early in the curing process to form a neat joint before the natural cracking occurs or by limiting the width of the slab being placed. Due to the difficulties of constructing good-performing keyed longitudinal joints, their use is not recommended. Tied longitudinal construction joints should be used in lieu of keyed longitudinal joints.

Typical BLRS practice requires the use of a deformed tie bar at all longitudinal joints. The basic purposes of tying the longitudinal joint are to provide load transfer and prevent lane separation. However, for pavement cross-sections greater than 60 ft wide, including turn lanes, shoulders, and medians, tying the entire width together may promote longitudinal cracking. For pavement cross sections in excess of 60 ft, use of dowel bars in lieu of deformed tie bars at one or more longitudinal joints may be an option. In situations where curb and gutter is present on both sides of the pavement, the confining pressure exhibited may preclude the need for tie bars across all longitudinal joints. In these cases, one or more longitudinal joints should not be tied as appropriate. Local experience may vary in these situations. If it can be determined that lane separation in pavements of similar thickness and cross section has not been a problem, a variance may be requested. The Central BLRS should be consulted for variances to the use of tie bars across longitudinal joints.

37-2.02(h) Subgrade

Roadbed soils that are susceptible to excessive volume changes, permanent deformation, excessive deflection and rebound, frost heave, and/or non-uniform support can affect pavement performance. For Class I and II roads, the designer is required to follow the guidelines found in Section 37-7. Use of Section 37-7 is optional for all Class III and IV roadways. In situ soils that do not develop an IBV in excess of 6.0 when compacted at, or wet of, optimum moisture content, require corrective action. The designer should consider corrective actions (e.g., undercutting, moisture density control, soil modification) in the design plans and specifications. The county soil report can be a useful source of typical soil information (e.g., standard dry density and optimum moisture content (AAHSTO T99), soil classification, percent clay, PI).

Necessary corrective actions as required by Section 37-7 will be in addition to the subbase requirements of the pavement design.

37-2.02(i) Subgrade Support Rating

The general physical characteristics of the roadbed soil affect the design thickness and performance of the pavement structure. For pavement design purposes, there are 3 subgrade support ratings (SSR) — poor, fair, and granular. The SSR is determined by using geotechnical grain size analysis and Figure 37-6A. The SSR should represent the average or majority classification within the design section. Figure 37-6A assumes a high water table and a frost penetration depth typical of an Illinois subgrade soil. For small projects, the SSR may be estimated by using USDA county soil reports or assumed to be poor. The pavement thickness design curves (Figures 37-2D and 37-2E) are based on a SSR of fair. Adjustments in the design thickness need to be made for the poor and granular subgrades.

37-2.02(j) Subbase

A subbase under a pavement serves two purposes. Initially it provides a stable construction platform for the subsequent courses. After construction it can improve the pavement

BUREAU OF LOCAL ROADS & STREETS

Jan 2006

PAVEMENT DESIGN

37-2(9)

performance by alleviating pumping of fine-grained soils and providing positive drainage for the pavement system. The usage and thickness requirements are given in Figure 37-2G.

When placing a PCC pavement directly over a flexible pavement with a HMA surface, consult Central BLRS for design assistance.

Road Class	Subbase Material	Usage ⁽¹⁾	Minimum Thickness (in)
Class I and II	Stabilized Subbase ⁽²⁾	Required	4
Class III and IV	Granular ⁽³⁾ , $TF \geq 0.7$	Required	4
	Granular ⁽³⁾ , $TF < 0.7$	Optional	4

Notes:

1. Subbase will be optional for urban sections having curbs and gutters and storm sewer systems. A 4 in minimum subbase may be used to serve as a working platform where poor soil conditions exist.
2. Stabilized subbase according to the requirements of the IDOT Standard Specifications or any applicable special provision.
3. Use Type A granular subbase according to the requirements of the IDOT Standard Specifications.

SUBBASE REQUIREMENTS**Figure 37-2G****37-2.02(k) Design Reliability**

Design reliability is taken into account through traffic multipliers applied to the design TF. These traffic multipliers are built into the PCC slab thickness design curves in Figures 37-2D and 37-2E. Figures 37-2D and 37-2E contain curves for both high and medium reliability levels. The minimum reliability levels by class of road are given in Figure 37-2H.

Road Class	Minimum Reliability Levels	Reliability (%)
Class I and II	High	90's
Class III	Medium	70's and 80's
Class IV (Figure 37-2I)	Medium	70's and 80's

RELIABILITY LEVELS**Figure 37-2H**

37-2.03 Thickness Design

37-2.03(a) Minimum Design Thickness

Once all pavement thickness adjustments have been made, the final design thickness must be 6.5 in or greater.

37-2.03(b) Preadjusted Slab Thickness

The jointed pavement thickness design procedure is based on determining the preadjusted slab thickness of the rigid pavement, and then adjusting for shoulder type, subgrade support conditions, and anticipated overloads. The preadjusted rigid pavement slab thicknesses were developed for pavements with flexible or untied PCC shoulders and fair subgrade support. For Class I, II, and III pavements, the preadjusted slab thicknesses are determined from Figures 37-2D and 37-2E for joint spacing of 12.5 ft and 15 ft. If a specific joint spacing is not desired, evaluate slab thicknesses for both potential joint spacings.

For Class IV PCC pavements, Figure 37-2I provides the preadjusted slab thickness for a 12.5 ft joint spacing. Overloads and poor soil conditions have been taken into consideration when developing these thicknesses; therefore, no further overload adjustment is necessary. Do not reduce the pavement thickness below 6.5 in.

Joint spacings of 15 ft are not provided for Class IV pavements because the thicknesses would be less than 8.0 in; therefore, the maximum recommended joint spacing would be 12.5 ft.

HCV's/day	Slab Thickness for 12.5 ft Joint Spacing (in)
< 40	6.5 ⁽¹⁾
≥ 40	⁽²⁾

Notes:

1. *No reduction in thickness will be allowed.*
2. *Use the Class III TF equations or a TF of 0.5, whichever is greater, in conjunction with Figures 37-2D and 37-2E.*

CLASS IV PAVEMENT PREADJUSTED SLAB THICKNESS

Figure 37-2I

37-2.03(c) Slab Thickness Adjustments

Adjustments to the preadjusted slab thickness should be made based on the shoulder type, subgrade support, and anticipated overloads. The final design thickness is rounded to the next highest 0.25 in. In determining any adjustments, consider the following:

1. Shoulder Type. The preadjusted rigid pavement thickness is to be adjusted if the PCC pavement has one of the following shoulder types:

tied PCC slab, including tied PCC widening;
tied curb and gutter;
integral curb and gutter; and/or
extended lanes.

Tied PCC slab, tied curb and gutter, and extended lane shoulder types must be tied with No. 6 tie bars or larger in order to receive the pavement thickness adjustment. A No. 6 or larger bar is needed to ensure that load transfer is obtained between the pavement and curb/shoulder. Designers may specify smaller tie bars, but no deduction in pavement thickness will be allowed based on shoulder type.

Figure 37-2J provides the slab thickness adjustments that are required if a shoulder type listed above is specified.

Slab Thickness (in)	Thickness Adjustment (in)
≥ 8.00	- 0.500
7.50 - 7.99	- 0.375
7.00 - 7.49	- 0.250
6.50 - 6.99	- 0.125

Note: No thickness adjustment is made for flexible or untied PCC shoulders. The designer should be aware of the potential for frost heave if flexible or untied shoulders are used.

SHOULDER TYPE ADJUSTMENT FACTORS

Figure 37-2J

BUREAU OF LOCAL ROADS & STREETS

37-2(12)

PAVEMENT DESIGN

Jan 2006

2. Subgrade Support. Pavement thickness adjustments are based on the subgrade support and whether the pavement structure will have a subbase or not. Figure 37-2K provides the subgrade support adjustment factors.

SSR	Adjustment with Subbase (in)	Adjustment without Subbase* (in)
Poor	0	+0.25
Fair	-0.25	0
Granular	-0.25	-0.25
Existing pavement	-0.25	-0.25

* *A subbase is optional for all Class III and IV pavements with a TF < 0.7, and for urban sections having curb and gutter and storm sewer systems.*

SUBGRADE SUPPORT ADJUSTMENT FACTORS**Figure 37-2K**

3. Overloads. The PCC pavement thickness can be adjusted for the number of anticipated overloads per week by using Figure 37-2L. Overloads are those loads that are anticipated to exceed the load limits from which the design TF's were developed. The rigid pavement design procedure is based on 18 kip Equivalent Single Axle Loads (ESAL's) and 80 psi tire pressure conditions. Typical overloads are created from permit loads and commercial, garbage, construction, and farm trucks, as well as, buses and some farm implements. No overload correction is necessary if the TF is greater than 2.0.

Projects adjacent to an industrial site with HCV's entering and leaving the site should be referred to the Central BLRS for special analysis.

Figure 37-2I has already taken overloads into consideration for Class IV pavements and no further overload adjustment is necessary.

After all necessary adjustments to the preadjusted slab thickness have been made, the designer should round the final design thickness to the next highest 0.25 in. The designer should compare the recommended design thicknesses to Figure 37-2F to determine which joint spacing is allowed.

OVERLOAD ADJUSTMENTS
(Number of Vehicles Equivalent to a Heavy Garbage Truck)

Figure 37-2L

37-2.03(d) Dowel Bars

Dowel bars must be used in all pavements with a TF of 3.0 or greater. Dowel bar diameter requirements are given in Figure 37-2M.

Slab Thickness (in)	Dowel Diameter (in)
≥ 8.00	1.5
7.00 to 7.99	1.25
< 7.00	1.0

37-2.04 Example Calculation

* * * * *

Example 37-2.1

Given: Class I, one-way urban street
 Design Period: 20 years
 Design Traffic:
 ADT: 8900
 94% PV (8366), 5% SU (445), 1% MU (89)
 73,280 lb. load limit
 Subgrade Support Rating: poor
 Shoulders: tied curb and gutter
 Overload vehicles: 5 per week

Problem: Design a jointed concrete pavement for the given conditions.

Solution:

1. Use Figure 37-2B and determine the TF equation for a one-way Class I pavement with a 73,280 lb load limit.

One-way Streets and Pavements (Rural and Urban)

$$TF = DP \frac{((0.073 \text{ PV}) + (58.035 \text{ SU}) + (274.665 \text{ MU}))}{1,000,000}$$

$$TF = 20 \left[\frac{(0.073 \times 8366) + (58.035 \times 445) + (274.665 \times 89)}{1,000,000} \right]$$

$$TF = 1.02$$

2. Because the pavement is a Class I road with tied curb and gutter, a subbase is optional; see Figure 37-2G, Note 1. For this example, assume a subbase is used. From Figure 37-2G, the minimum subbase requirement is 4 in. Dowels or aggregate interlock are design options because the TF is less than 3.0; see Section 37-2.03(d).
3. Because this is a Class I facility, the high-reliability curves of Figures 37-2D and 37-2E should be used. The preadjusted slab thicknesses for fair subgrade support, flexible shoulders, and high reliability are:

Transverse Joint Spacing (ft)	Preadjusted Thickness (in)
12.5	7.10
15.0	7.45

BUREAU OF LOCAL ROADS & STREETS

Jan 2006

PAVEMENT DESIGN

37-2(19)

4. Pavement thickness adjustments for tied curb and gutter are listed below based on the preadjusted pavement thickness determined above and the shoulder adjustment factors; see Figure 37-2J.

Transverse Joint Spacing (ft)	Adjustments for Shoulder Type (in)
12.5	deduct 0.250
15.0	deduct 0.250

5. Pavement thickness adjustments for subgrade support are based on the SSR and whether the pavement structure will have a subbase or not. Assuming a stabilized subbase, no pavement thickness adjustment is required for a pavement with a poor SSR; see Figure 37-2K.

Note that if the designer had opted not to use a stabilized subbase, a pavement thickness adjustment of plus 0.25 in would be required.

6. Pavement thickness adjustments (increases) for overloads can be taken directly from Figure 37-2L. An adjustment of +0.09 in is necessary for a pavement structure where five overloaded vehicles per week are anticipated in conjunction with a design TF of 1.02.
7. Adjustments of the preadjusted pavement thicknesses for the different transverse joint spacing are summarized as follows:

Transverse Joint Spacing	Preadjusted Thickness	Adjustments			Final Thickness
		Shoulder	Subgrade	Overloads	
12.5 ft	7.10 in	- 0.250 in	0 in	+0.09 in	6.94 in
15.0 ft	7.45 in	- 0.250 in	0 in	+0.09 in	7.29 in

8. The designer should round the final design thicknesses up to the next highest 0.25 in. Therefore, the recommended design thicknesses for the preceding joint spacing are:

Transverse Joint Spacing (ft)	Recommended Thickness (in)
12.5	7.00
15.0	7.50

9. Because the recommended slab thickness is less than 8.0 in, a maximum transverse joint spacing of 12.5 ft should be used per Figure 37-2F.

* * * * *

37-3 CONVENTIONAL FLEXIBLE PAVEMENT DESIGN FOR LOCAL AGENCIES

37-3.01 Introduction

A conventional flexible pavement is a HMA surface in combination with a granular base and, if required, additional subbase layers. Conventional flexible pavements are allowed for traffic factors (TF) up to 0.25.

The design criteria for conventional flexible pavements are HMA fatigue and subgrade stress. A Subgrade Stress Ratio (SSR) criterion is used to accommodate subgrade rutting considerations. The conventional flexible design procedure is based on 18 kip Equivalent Single Axle Loads (ESAL's) and 80 psi tire pressure conditions.

37-3.02 Basic Design Elements

37-3.02(a) Classes of Roads and Streets

The class of the road or street for which the pavement structural design is being determined is dependent upon the structural design traffic. These road classifications are defined in Section 37-1.

37-3.02(b) Minimum Material Requirements

HMA binder and surface course are required for conventional flexible pavement design. Use a minimum thickness of 3 in of HMA.

Use a minimum thickness of 8 in of Type A aggregate base material. A modified soil layer (8 in minimum) or Type B granular subbase material (4 in minimum) may be used at a 1:1 ratio to satisfy granular layer thickness requirements in excess of 8 in. For example, a 12 in base requirement could be satisfied by using 12 in of Type A aggregate base material or 8 in of Type A and 4 in of Type B aggregate material.

Class IV pavements with less than 20 HCV's per day may use Type B granular base material in place of Type A granular base material for the entire base thickness required.

37-3.02(c) Design Period

The design period DP is the length of time in years that the pavement is being designed to serve the structural design traffic. For conventional flexible pavements, the minimum DP allowed is 20 years for Class I and II roads and streets. For Class III roads and streets, a minimum DP of 15 years is allowed. For Class III roads and streets, designers are encouraged to determine thicknesses for both 15 year and 20 year DP's prior to selecting the final design thickness. In most cases, going from a 15 year design to a 20 year design requires only 0.5 in to 1 in of additional HMA.

BUREAU OF LOCAL ROADS & STREETS

37-3(2)

PAVEMENT DESIGN

Jan 2006

Class IV pavement thicknesses provided in Section 37-3.03(b) should be satisfactory for DP's of 15 years or 20 years.

37-3.02(d) Structural Design Traffic

The structural design traffic is the estimated ADT for the year representing one-half of the design period. For example, when the design period is 20 years, the structural design traffic will be an estimate of the ADT projected to 10 years after the construction date.

The structural design traffic is estimated from current traffic count data obtained either by manual counts or from traffic maps published by IDOT. If PV, SU, and MU counts are not available for Class III and IV roads and streets, Figure 37-3A provides an estimate of counts that can be made from the component percentages of the total traffic.

Class of Road or Street	Percentage of Structural Design Traffic		
	PV (%)	SU (%)	MU (%)
III	88	7	5
IV	88	9	3

**PERCENTAGE OF STRUCTURAL DESIGN TRAFFIC
(Class III or IV)**

Figure 37-3A

37-3.02(e) Traffic Factors

The maximum allowable Traffic Factor (TF) for conventional flexible pavements is 0.25. For Class I, II, and III roads and streets, the design TF for flexible pavements can be determined for various DP's from the 73,280 lb and 80,000 lb load limit formula shown in Figures 37-3B and 37-3C respectively. The formulas shown are based on the statewide average distribution of vehicle types and axle loadings, which are directly applicable to most roads and streets.

However, cases will arise in which the average formula should not be used (e.g., a highway where HCV's entering and leaving a site generally travel empty in one direction and fully loaded in the other). These cases should be referred to the Central BLRS for special analysis. The local agency must provide the Central BLRS with the structural design traffic; the DP; traffic distribution by PV, SU, and MU; and loading condition of HCV traffic.

For Class IV roads and streets, thicknesses are provided in Section 37-3.03(b) based on the daily volume of HCV's; therefore, a design TF is not necessary.

37-3.02(f) Stage Construction

Stage construction is the planned construction of the pavement structure in two or more stages. Stage construction will be allowed on conventional flexible pavements with a design TF greater than 0.1 and with the approval of the district. The maximum time period that may elapse between the completion of the first stage and the scheduled construction date of the final stage is 2 years.

If HMA (base or surface course) is part of the initial stage, provide a minimum HMA thickness of 3 in. The total HMA thickness resulting from the stages will be the HMA design thickness plus an additional 0.5 in.

If a HMA mixture is not part of the initial stage, place an A-2 or A-3 surface treatment over the aggregate base. The aggregate base thickness will be determined on a project-by-project basis by the Central BLRS.

Any evidence of fatigue cracking, raveling, or other deterioration prior to the construction of the final stage will necessitate a re-evaluation of the structural design of the pavement.

37-3.02(g) PG Binder Grade Selection

The PG binder grade may affect the performance of a HMA mixture. The conventional flexible pavement design procedure assumes that HMA rutting and thermal cracking are adequately considered in the material selection and mixture design process. Selection of the appropriate binder grade can impact the ability of the mix to resist rutting at higher temperatures and thermal cracking at lower temperatures. Both high and low temperature levels need to be considered when selecting the appropriate binder grade for conventional flexible pavements.

Conventional flexible pavements should use the grades shown in Figures 37-3D and 37-3E. Most conventional flexible pavements should use the grades shown for a standard traffic level. Areas of slow moving or standing traffic (e.g., intersections, bus stops, city streets) warrant the use of stiffer binders to resist rutting. PG binder grade adjustments should be made according to Figures 37-3E and 37-3F for the corresponding N_{design} number, provided by the district, and/or design ESALs. PG binder grade adjustments, where applicable, should be applied to the surface and top binder lift.

Binder grade adjustments may also be warranted based on the use of reclaimed asphalt pavement (RAP) in the mix. For mixtures containing a minimum of 15% RAP, both the high and low temperature binder grades should be decreased by one grade equivalent (e.g., if use of PG 64-22 is specified for a virgin aggregate mix, a PG 58-28 should be used for a mix containing a minimum of 15% RAP). The appropriate grade of binder should be reported on the plans.

The local agency must request a variance from the Central BLRS to use a different PG binder than that specified in Figure 37-3D and Figure 37-3E.

BUREAU OF LOCAL ROADS & STREETS
PAVEMENT DESIGN

Jan 2006

37-3(5)

PG Binder Grade Selection ^{(1) (2)}			
HMA	Traffic Loading Rate		
	Standard ⁽³⁾	Slow ⁽⁴⁾	Standing ⁽⁵⁾
Surface	PG 58-28	PG 64-28, SBR PG 64-28 ⁽⁶⁾ , or SBS PG 64-28	SBR PG 70-28 ⁽⁶⁾ or SBS PG 70-28
Top Binder Lift	PG 58-28	PG 64-28, SBR PG 64-28 ⁽⁶⁾ , or SBS PG 64-28	SBR PG 70-28 ⁽⁶⁾ or SBS PG 70-28
Lower Binder Lifts	PG 58-22	PG 58-22	PG 58-22

Notes:

1. *The binder grades provided in Figure 37-3D are based on the recommendations given in Illinois-Modified AASHTO MP-2, Table 1, "Binder Selection on the Basis of Traffic Speed and Traffic Level."*
2. *For mixtures containing a minimum of 15% RAP, both the high and low temperature binder grades should be decreased by one grade equivalent. For example, if use of a PG 64-22 is specified for a virgin aggregate mix, a PG 58-28 should be used for a mix containing a minimum of 15% RAP. Mixtures containing less than 15% RAP should use the binder grade specified in the above table.*
3. *Standard traffic is used where the average traffic speed is greater than 43 mph (70 km/h).*
4. *Slow traffic is used where the average traffic speed ranges from 12 to 43 mph (20 to 70 km/h).*
5. *Standing traffic is used where the average traffic speed is less than 12 mph (20 km/h).*
6. *SBR modified binders are not available in Illinois at this time.*

PG BINDER GRADE SELECTION FOR CONVENTIONAL FLEXIBLE PAVEMENTS

PG Binder Grade Selection ^{(1) (2)}			
HMA	Traffic Loading Rate		
	Standard ⁽³⁾	Slow ⁽⁴⁾	Standing ⁽⁵⁾
Surface	PG 64-22	PG 70-22, SBR PG 70-22 ⁽⁶⁾ , or SBS PG 70-22	SBR PG 76-22 ⁽⁶⁾ or SBS PG 76-22
Top Binder Lift	PG 64-22	PG 70-22, SBR PG 70-22 ⁽⁶⁾ , or SBS PG 70-22	SBR PG 76-22 ⁽⁶⁾ or SBS PG 76-22
Lower Binder Lifts	PG 64-22	PG 64-22	PG 64-22

Notes:

- The binder grades provided in Figure 37-5E are based on the recommendations given in Illinois-Modified AASHTO MP-2, Table 1, "Binder Selection on the Basis of Traffic Speed and Traffic Level".*
- For mixtures containing a minimum of 15% RAP, both the high and low temperature binder grades should be decreased by one grade equivalent. For example, if use of a PG 64-22 is specified for a virgin aggregate mix, a PG 58-28 should be used for a mix containing a minimum of 15% RAP. Mixtures containing less than 15% RAP should use the binder grade specified in Figure 37-5F.*
- Standard traffic is used where the average traffic speed is greater than 43 mph (70 km/h).*
- Slow traffic is used where the average traffic speed ranges from 12 to 43 mph (20 to 70 km/h).*
- Standing traffic is used where the average traffic speed is less than 12 mph (20 km/h).*
- SBR modified binders are not available in Illinois at this time.*

PG BINDER GRADE SELECTION FOR CONVENTIONAL FLEXIBLE PAVEMENTS
(Districts 5-9)

Figure 37-3E

37-3.02(h) Subgrade Inputs

The general physical characteristics of the roadbed soils affect the design thickness and performance of the pavement structure. For full-depth HMA pavements, the thickness of the pavement structure is sufficient to reduce the subgrade vertical compression stresses to an acceptable level. An improved subgrade under a full-depth HMA pavement functions primarily as a working platform. However, in conventional flexible pavement design, the roadbed soil plays a critical role in the load-carrying capacity of the pavement. Therefore, a careful examination of the subgrade soil characteristics is necessary.

For the design of conventional flexible pavement, the critical subgrade modulus (E_{Ri}) is used. The critical E_{Ri} is the expected spring season E_{Ri} value (usually when the water table is highest and after the spring thaw). The critical E_{Ri} can be determined using one of the methods outlined in Section 37-6.

E_{Ri} values less than 2 ksi require subgrade stabilization. Subgrade soils suspected of having modulus values this low require a soils investigation.

The designer should take into consideration the susceptibility of the roadbed soil to excessive volume changes, permanent deformation, excessive deflection and rebound, frost heave, and non-uniform support. The designer should use Section 37-7 to address these types of issues by recommending corrective actions (e.g., undercutting, moisture density control, soil modification) in the design plans and specifications. The special provision entitled "Soil Modification" should be used in lieu of the "Lime-Modified Soils" section of the *IDOT Standard Specifications*. Necessary corrective measures would be in addition to the subbase requirements of the pavement design.

Pavement thickness adjustments are not necessary for sandy/granular subgrade materials, which typically have a modulus greater than 3 ksi. The designer is cautioned against assuming an E_{Ri} value greater than 3 ksi if there are no test results to support the assumption.

37-3.02(i) Base and Subbase

A subbase under a pavement serves two purposes. Initially, it provides a stable construction platform for the base and surface courses. After construction, it can improve the pavement performance by alleviating pumping of fine-grained soils and providing positive drainage for the pavement system.

1. Thickness. Use a minimum thickness of 8 in. of Type A aggregate base material. For granular layer thickness requirements in excess of 8 in, The minimum 8 in Type A aggregate base material would still be required, but additional base thickness requirements could be satisfied by using a minimum 4 in Type B granular subbase material or a minimum 8 in modified soil layer.

BUREAU OF LOCAL ROADS & STREETS

37-3(8)

PAVEMENT DESIGN

Jan 2006

Class IV pavements with less than 20 HCV's per day may use Type B aggregate base material in place of Type A aggregate base material for the entire base thickness required.

2. Width. Aggregate subbase and base course shall be at least 2 feet wider than the HMA surface course. If curb and gutter is used, this may be reduced to 1 foot.

37-3.02(j) Design Reliability

Design reliability is taken into account through traffic factor multipliers applied to the design TF. These traffic multipliers are built into the HMA design strain curve in Figure 37-3I. The minimum reliability levels by class of road are given in Figure 37-3F

Road Class	Minimum Reliability Level	Reliability (%)
Class I, II, III, and IV	Medium	70's and 80's

RELIABILITY LEVEL**Figure 37-3F**

Note: The estimated percent reliability is based on a representative 9-kip Falling Weight Deflectometer surface deflection coefficient of 25%.

37-3.03 Thickness Design — Superpave Mixtures**37-3.03(a) Class I, II, and III Roads and Streets**

The following applies to types of facilities using Superpave mixtures:

1. HMA Design Mixture Temperature. The HMA mixture temperatures are given in Figure 37-3G based on geographic locations in Illinois. The design mixture temperature should be interpolated to the nearest 0.5°F. The minimum design mixture temperature is 72°F.

Note: Design Time dates are not the same for conventional flexible and full-depth HMA pavements. Conventional flexible design time dates occur earlier in the spring. Therefore, for the same location, the conventional flexible HMA design mixture temperature is lower than the full-depth HMA design mixture temperature. Figure 37-3G of the conventional flexible pavement design is not the same as Figure 37-4G in the full-depth pavement design procedure.

2. HMA Design Modulus (E_{AC}). The design E_{AC} is the HMA modulus that corresponds to the design mixture temperature. Determine the design E_{AC} value from Figure 37-3H for typical Superpave mixtures with PG 52-XX, PG 58-XX, PG 64-XX, or PG 70-XX.

3. HMA Design Strain. The HMA design strain is the tensile strain at the bottom of the HMA pavement layer. Use Figure 37-3I in conjunction with the design TF to determine the design strain.
4. Thickness Requirements. Use Figure 37-3J in conjunction with the HMA design strain from Step 3 to determine the thickness of Superpave mixture required. The thicknesses from Figure 37-3J are based on an 8 in minimum Type A aggregate base thickness and an E_{Ri} of 3 ksi.
5. Subbase Thickness Adjustments. The fine-grained soils that predominate in Illinois commonly have an E_{Ri} greater than 3 ksi. For pavements with an E_{Ri} of 3 ksi or greater, an 8 in Type A aggregate base is structurally adequate; therefore, no pavement structure thickness adjustment is necessary. For subgrades with an E_{Ri} value equal to or greater than 2 ksi and less than 3 ksi, Figure 37-3K should be used to determine the appropriate structure enhancement category for the pavement. Subgrades with an E_{Ri} less than 2 ksi must follow Section 37-7.

37-3.03(b) Class IV Roads and Streets Thickness Requirements

Figures 37-3L and 37-3M provide the HMA and aggregate base thicknesses for various E_{Ri} values and traffic levels. Pavements with less than 20 HCV's per day may use Type B aggregate base material in lieu of Type A aggregate base material.

When 4 in or more of HMA are used, 8 in of Type A aggregate base material is satisfactory for all combinations of soil types and traffic levels for all districts.

37-3.04 Typical Sections

Figures 37-3N and 37-3O illustrate typical local agency rigid pavement designs.

BUREAU OF LOCAL ROADS & STREETS
PAVEMENT DESIGN

37-3(14)

Jan 2006

Original HMA Design Thickness (in)	HMA Design Modulus, E_{AC} (ksi)				
	400	500	600	700	800
3.0 – 3.49	$E^{(2)}$	$E^{(2)}$	$E^{(2)}$	$E^{(1)}$	$E^{(1)}$
3.5 – 3.99	$E^{(2)}$	$E^{(1)}$	$E^{(1)}$	O	O
≥ 4.0	O	O	O	O	O

E: Enhancement of the pavement structure is required.

O: Enhancement of the pavement structure is optional. If no enhancement is desired, an 8 in Type A aggregate base course is required.

Notes: If the subgrade E_{Ri} is less than 2 ksi, use Section 37-7 to determine the appropriate subgrade treatment necessary.

A pavement structure consisting of an 8 in Type A aggregate base course, based on the appropriate category from the above table, can be enhanced by one of the following alternatives:

1. $E^{(1)}$. Use one or more of the following:
 - Increase the HMA thickness by 0.5 in.
 - Increase the Type A aggregate base thickness by 2 in.
 - Add a 4 in minimum Type B granular subbase.
 - Add an 8-in minimum modified soil layer.
2. $E^{(2)}$. Use one or more of the following:
 - Increase the HMA thickness by 1.0 in.
 - Increase the Type A aggregate base thickness by 4 in.
 - Add a 4 in minimum Type B granular subbase.
 - Add an 8-in minimum modified soil layer.

Example Calculations

Example 37-3.1

Given: Class III, two-lane pavement
 DP: 20 years
 Design Traffic:
 ADT: 420
 85% PV (357), 10% SU (42), 5% MU (21)
 73,280 lb load limit

 Location: Urbana, IL
 Critical Subgrade E_{Ri} : 3 ksi
 Posted Speed Limit: 45 mph

Problem: Design a conventional flexible pavement with a HMA surface for the given conditions.

Solution:

1. From Figure 37-3B, use the TF equation for a two-lane Class III pavement with a 73,280 lb load limit.

2 or 3-Lane Pavements:

$$TF = DP \frac{(0.073 PV) + (44.350 SU) + (154.943 MU)}{1,000,000}$$

$$TF = 20 \frac{(0.073 \times 357) + (44.350 \times 42) + (154.943 \times 21)}{1,000,000}$$

$$TF = 0.103$$

2. HMA design mixture temperature from Figure 37-3G is 76.5°F.
3. From Figure 37-3E, use a PG 64-22 due to a standard traffic loading rate. The HMA design modulus (E_{AC}) from Figure 37-3H would be 640 ksi.
4. The HMA design strain from Figure 37-3I would be 290 microstrain.
5. HMA thickness from Figure 37-3J is 3.5 in.
6. The final design would be 3.5 in HMA surface + 8 in Type A aggregate base (8 in minimum Type A aggregate base is satisfactory because E_{Ri} = 3 ksi.)

Example 37-3.2

Given: Class II, two-lane pavement
 DP: 20 years
 Design Traffic:
 ADT: 3015
 97% PV (2925), 2% SU (60), 1% MU (30)
 73,280 lb load limit
 Location: Chicago
 Critical Subgrade E_{Ri} : 2 ksi
 Posted speed limit: 30 mph (no standing traffic)

Problem: Design a conventional flexible pavement with HMA surface for the given conditions.

Solution:

1. From Figure 37-3B, use the TF equation for a two-lane Class II pavement with a 73,280 lb load limit.

2 or 3 Lane Pavements:

$$TF = DP \frac{(0.073 \text{ PV}) + (44.530 \text{ SU}) + (156.403 \text{ MU})}{1,000,000}$$

$$TF = 20 \frac{(0.073 \times 2925) + (44.530 \times 60) + (156.403 \times 30)}{1,000,000}$$

$$TF = 0.15$$

2. A PG 64-28, SBR 64-28, or SBS 64-28 grade of asphalt binder should be used to compensate for the stopping and starting traffic patterns common in urban areas.
3. The HMA design mixture temperature from Figure 37-3G is 73°F.
4. The HMA design modulus (E_{AC}) from Figure 37-3H is 750 ksi.
5. The HMA design strain from Figure 37-3I would be 256 microstrain.
6. HMA thickness from Figure 37-3J is 4 in. Figure 37-3J is based on an 8 in Type A aggregate base and an E_{Ri} value of 3 ksi or greater. Because the E_{Ri} value is 2 ksi, Figure 37-3K must be used to determine if any pavement thickness enhancements are necessary.

BUREAU OF LOCAL ROADS & STREETS

37-3(20)

PAVEMENT DESIGN

Jan 2006

7. Figure 37-3K designates the pavement thickness adjustment requirement as a category "O" (4.0 in HMA thickness and 700 ksi E_{ac}). Enhancement of the pavement structure is optional.
8. The final design would be 4 in of Superpave mixture and 8 in of Type A aggregate base material. The designer could opt to enhance the pavement structure by increasing the HMA thickness or the aggregate base thickness or by using a modified soil layer.

Example 37-3.3

Given: Class IV, 2-lane pavement
DP: 15 years
Design Traffic:
ADT: 350
94.5% PV (331), 3.5% SU (12), 2% MU (7)
73,280 lb load limit
Critical Subgrade E_{Ri} : 2.5 ksi
Location: District 5

Problem: Design a conventional flexible pavement with a HMA surface for the given conditions.

Solution:

Because this is a Class IV street, Figure 37-3L and Figure 37-3M should be used. With 19 HCV's (SU's + MU's) per day and critical subgrade E_{Ri} of 2.5 ksi, the designer will need to decide if a thicker HMA surface or thicker aggregate base is appropriate. A thicker aggregate base is usually less expensive; therefore, Figure 37-3L is used. A 3 in HMA surface over an 11 in Type A aggregate base is required; however, because HCV's < 20, Type B aggregate base material may be substituted for Type A aggregate base material.

* * * * *

37-4 FULL-DEPTH HMA PAVEMENT DESIGN FOR LOCAL AGENCIES

37-4.01 Introduction

37-4.01(a) Design of Full-Depth HMA Pavements

Full-depth HMA pavements are those pavement structures whose surface and principal load-carrying component is HMA. This design procedure assumes that HMA rutting and thermal cracking are adequately considered in the material selection and mixture design process. The design procedure controls subgrade rutting by limiting the deviator stress at the HMA-subgrade interface to an acceptable level. The governing design criteria is the HMA tensile strain. Reduced strain corresponds to increased fatigue life.

37-4.01(b) Usage of Procedure

Use the pavement design procedure in this Section for all local road and street projects where a full-depth HMA pavement is desired. If the local agency intends to transfer jurisdiction following pavement construction, both agencies involved in the jurisdictional transfer should agree on the design.

The pertinent charts, tables, equations, limitations, and requirements of the policy are included in this procedure, as well as specific instructions to be followed in applying the method of design to full-depth HMA pavements for local agency projects involving MFT and Federal funds. Do not use this procedure for the design of projects on the State Highway System.

When small quantities of pavement are to be constructed, a soil investigation is not required, unless field conditions warrant. Small quantities are considered to be as follows:

- less than one city block in length,
- less than 3000 yd², or
- widening less than one lane-width.
- When small quantities are to be constructed adjacent to or in extension of an existing pavement, the designer should:
 - design a new section assuming a poor subgrade support rating, and
 - provide a minimum thickness of 6.0 in.

BUREAU OF LOCAL ROADS & STREETS

37-4(2)

PAVEMENT DESIGN

Jan 2006

37-4.02 Basic Design Elements**37-4.02(a) Minimum Material Requirements**

HMA surface and binder courses are allowed. Any combination of surface course or binder course may be used to arrive at the total HMA design thickness. However, for economic reasons, a minimum surface course thickness of 1.5 in should be used unless the designer has compelling reasons to deviate.

37-4.02(b) Classes of Roads and Streets

The class of the road or street for which the pavement structure is being designed depends on the structural design traffic and is described in Section 37-1.

37-4.02(c) Design Period

The design period (DP) is the length of time in years that the pavement is being designed to serve the structural design traffic. For Class I and II roads and streets, a DP of 20 years should be used. For Class III roads and streets, a minimum DP of 15 years is allowed. The pavement thickness provided for Class IV pavements with 40 or less HCV's should be satisfactory for a 15 year or 20 year DP.

37-4.02(d) Structural Design Traffic

The structural design traffic is the estimated ADT for the year representing one-half of the design period. For example, when the design period is 20 years, the structural design traffic will be an estimate of the ADT projected to 10 years after the construction date.

The structural design traffic is estimated from current traffic count data obtained either by manual counts or from traffic maps published by IDOT. If PV, SU, and MU counts are not available for Class III and IV roads and streets, Figure 37-4A provides an estimate of counts that can be made from the component percentages of the total traffic.

Class of Road or Street	Percentage of Structural Design Traffic		
	PV (%)	SU (%)	MU (%)
III	88	7	5
IV	88	9	3

**PERCENTAGE OF STRUCTURAL DESIGN TRAFFIC
(Class III or IV)**

Figure 37-4A

37-4.02(e) Traffic Factors

For Class I, II, and III roads and streets, the design Traffic Factor (TF) for flexible pavements can be determined for various DP's and Classes of roads and streets from the 73,280 lb and 80,000 lb load limit formulas in Figures 37-4B and 37-4C, respectively. The formulas shown are based on the Statewide average distribution of vehicle types and axle loadings, which are directly applicable to most roads and streets.

However, cases will arise in which the average formula should not be used (e.g., a highway where HCV's entering and leaving a site generally travel empty in one direction and fully loaded in the other). These cases should be referred to the Central BLRS for special analysis. The local agency must provide the Central BLRS with the structural design traffic, the DP, traffic distribution by PV, SU, MU, and loading conditions of HCV traffic.

For Class IV roads and streets, thicknesses are determined based on the volume of HCV's per day. Therefore, a design TF is not necessary.

Class I Roads and Streets	
4 or 5 Lane Pavements (Rural and Urban)	$TF = DP \frac{(0.047 PV + 47.961 SU + 169.178 MU)}{1,000,000}$
6 or More Lane Pavements (Rural)	$TF = DP \frac{(0.029 PV + 42.632 SU + 150.380 MU)}{1,000,000}$
6 or More Lane Pavements (Urban)	$TF = DP \frac{(0.012 PV + 39.435 SU + 139.102 MU)}{1,000,000}$
One-way Streets and Pavements (Rural and Urban)	$TF = DP \frac{(0.073 PV + 53.290 SU + 187.975 MU)}{1,000,000}$
Class II Roads and Streets	
2 or 3 Lane Pavements	$TF = DP \frac{(0.073 PV + 44.530 SU + 156.403 MU)}{1,000,000}$
Class III Roads and Streets	
2 or 3 Lane Pavements	$TF = DP \frac{(0.073 PV + 44.350 SU + 154.943 MU)}{1,000,000}$

Class III Roads and Streets	
2 or 3 Lane Pavements	$TF = DP \frac{(0.073 PV + 54.57 SU + 192.175 MU)}{1,000,000}$

FLEXIBLE TRAFFIC FACTOR EQUATIONS (80,000 LB LOAD LIMIT)

Figure 37-4C

37-4.02(f) Subgrade Support Rating

There are three subgrade support ratings used in this design procedure — poor, fair, and granular. The designer should use Figure 37-6A in conjunction with the soil grain size analysis to determine the subgrade support rating. The subgrade support rating should represent the average or majority rating classification within the design section. Figure 37-6A assumes a high water table and appropriate frost penetration in the subgrade soil. For some small projects, in the absence of laboratory tests, the subgrade support rating may be estimated by using the USDA county soil reports.

37-4.02(g) Subgrade Working Platform

Roadbed soils that are susceptible to excessive volume changes, permanent deformation, excessive deflection and rebound, frost heave, and/or non-uniform support can affect pavement performance. An improved subgrade layer provides a working platform and uniform support for pavement layer construction. Without the minimum required improved subgrade layer, it may be difficult to ensure adequate density in HMA. A modified soil layer or granular material may be used to satisfy the improved subgrade layer requirement. In urban areas, use of granular

BUREAU OF LOCAL ROADS & STREETS

Jan 2006

PAVEMENT DESIGN

37-4(5)

material may be more practical than a modified soil layer due to concerns about dust pollution. Subgrade working platform requirements are outlined in Figure 37-4D.

The improved subgrade layer will not be structurally credited in the design procedure. Its purpose is solely to provide a working platform on which to construct a quality pavement structure. A 12 in layer is adequate for this purpose in most, but not all cases. Use of additional improved layer thickness will not reduce the HMA pavement thickness.

Road Class	Improved Working Platform Material	Usage	Minimum Thickness (in)
Class I and II	Modified Soil Layer or Granular Material	Required ⁽¹⁾	12 ⁽³⁾
Class III and IV	Modified Soil Layer or Granular Material	Optional ⁽²⁾	12 ⁽³⁾

Notes:

1. *For Class I and II roads, a 12 in minimum improved subgrade layer is required, unless the existing subgrade is granular. Where an existing granular subgrade is encountered, the local agency may obtain a waiver to the subgrade working platform requirement from Central BLRS by documenting the subgrade suitability.*
2. For Class III and IV roads, the 12 in minimum improved subgrade layer is optional if documentation can be provided to the district that indicates the subgrade will provide suitable support during construction in accordance with Section 37-7. Because an improved subgrade layer should improve the constructability and possibly the performance of the pavement, its use should be considered.
3. In some cases, soft subgrades may require more than 12 in of improved subgrade to provide a stable working platform and uniform support. The designer should review Section 37-7 in order to determine the required thickness of improved subgrade.

SUBGRADE WORKING PLATFORM REQUIREMENTS**Figure 37-4D**

Lower Binder Lifts	PG 64-22	PG 64-22	PG 64-22

Notes:

1. The binder grades provided in this table are based on the recommendations given in Illinois-Modified AASHTO MP-2, Table 1, "Binder Selection on the Basis of Traffic Speed and Traffic Level."
2. For mixtures containing a minimum of 15% RAP, both the high and low temperature binder grades should be decreased by one grade equivalent. For example, if use of a PG 64-22 is specified for a virgin aggregate mix, a PG 58-28 should be used for a mix containing a minimum of 15% RAP. Mixtures containing less than 15% RAP should use the binder grade specified in the above table.
3. Standard traffic is used where the average traffic speed is greater than 43 mph (70 km/h).
4. Slow traffic is used where the average traffic speed ranges from 12 to 43 mph (20 to 70 km/h).
5. Standing traffic is used where the average traffic speed is less than 12 mph (20 km/h).
6. Consideration should be given to increasing the high temperature grade by one grade equivalent when $10 \leq T.F. \leq 30$. For example, if use of a PG 64-22 is specified for standard traffic, a PG 70-22, a SBR PG 70-22, or a SBS PG 70-22 should be specified.
7. The high temperature grade should be increased by one grade equivalent when $T.F. > 30$. For example, if use of a PG 64-22 is specified for standard traffic, a PG 70-22, a SBR PG 70-22, or a SBS PG 70-22 should be specified.
8. SBR-modified binders are not available in Illinois at this time.

PG BINDER GRADE SELECTION FOR FULL-DEPTH HMA PAVEMENTS
Figure 37-4E

37-4.02(h) PG Binder Selection

The PG binder grade may affect the performance of a HMA mixture. The full-depth HMA pavement design procedure assumes that HMA rutting and thermal cracking are adequately considered in the material selection and mixture design process. Selection of the appropriate binder grade can impact the ability of the mix to resist rutting at higher temperatures and thermal cracking at lower temperatures. Both high and low temperature levels need to be considered when selecting the appropriate binder grade for full-depth HMA pavements.

Full-depth HMA pavements should use the PG binder grades shown in Figure 37-4E. Most full-depth HMA pavements should use the grades shown for a standard traffic level. Adjustments to the standard traffic level are made if conditions of slow moving traffic or standing traffic warrant. Areas of slow moving or standing traffic, such as intersections or bus stops, warrant the use of stiffer binders to resist rutting and shoving. Adjustments, where applicable, have been applied to the surface and top binder lift. This keeps the same PG grade in these two lifts.

Binder grade adjustments may also be warranted based on extremely high ESALs levels, or the use of reclaimed asphalt pavement (RAP) in the mix. These adjustments should be made according to Note 2 and Note 6 in Figure 37-4E. The appropriate grade of binder should be reported on the plans.

Note: The PG binder grade selection tables for full-depth HMA pavements for local agency pavement design differ from the tables used for the state system. A lower level of reliability is used for local agency design than for the state system.

The local agency must request a variance from the Central BLRS to use a different PG binder than that specified in Figure 37-4E.

37-4.02(i) Stage Construction

Stage construction is the planned construction of the pavement structure in two or more stages. Stage construction is not allowed on full-depth HMA pavements.

37-4.02(j) Design Reliability

Design reliability is taken into account through traffic factor multipliers applied to the design TF. These traffic multipliers are built into the HMA design strain curves in Figures 37-4H and 37-4I. The minimum reliability levels by class of road are given in Figure 37-4F.

Road Class	Minimum Reliability Level	Reliability (%)
Class I, II, III, and IV	High	90's

DESIGN RELIABILITY
Figure 37-4F

37-4.03 Thickness Design

In determining the design thickness, consider the following:

1. Class I, II and III Roads and Streets. The design procedure is as follows:

- Calculate the TF from the appropriate equation found in Figures 37-4B and 37-4C.
- Use Figure 37-6A in conjunction with the subgrade soil grain-size analysis to determine the subgrade support rating.
- Use Figure 37-4E in conjunction with traffic speed and location to determine the PG binder grade.
- Use Figure 37-4G to determine the HMA pavement mixture temperature. The design mixture temperature should be interpolated to the nearest 0.5°F.

Note: The design time dates are not the same for full-depth HMA and conventional flexible pavements. Full-depth HMA design time dates occur later in the spring. Therefore, for the same location, the conventional flexible HMA design mixture temperature is lower than the full-depth HMA design mixture temperature. Figure 37-3G of the conventional flexible pavement design is not the same as Figure 37-4G in the full-depth pavement design procedure.

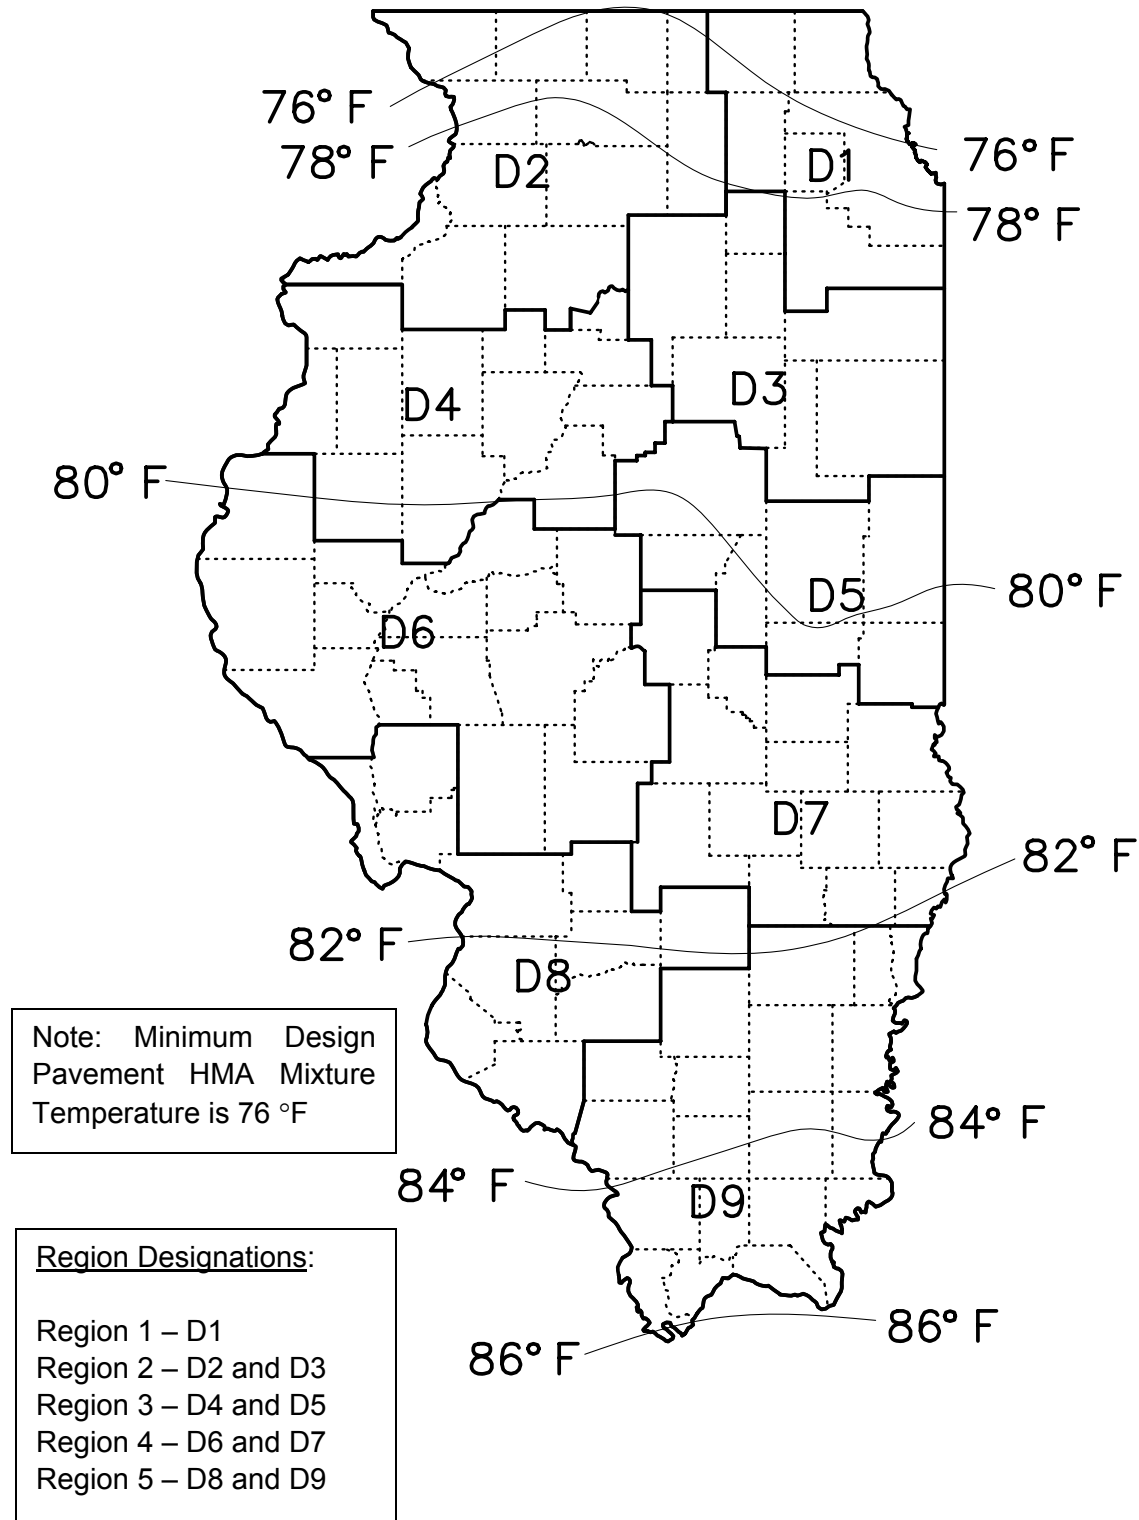

- Use Figure 37-4H (TF < 0.5) or Figure 37-4I (TF ≥ 0.5) to determine the HMA design strain.
- Use Figure 37-4J to determine the design pavement HMA modulus (E_{AC}).
- Use Figures 37-4K, 37-4L, or 37-4M, depending on the subgrade support rating, to determine the design HMA thickness. Round the final design thickness to the next highest 0.25 in.
- The minimum full-depth HMA design thickness is 6 in.
- A 12 in improved subgrade is required for Class I and II pavements and is optional for Class III pavements. Class III pavement subgrades must satisfy the requirements of Section 37-7 during construction.

2. Class IV Roads and Streets. The following procedure applies:

- If HCV's per day ≤ 40, use a minimum 6 in HMA pavement. A 12 in improved subgrade layer is optional. Class IV pavement subgrades must satisfy the requirements of Section 37-7 during construction.
- If HCV's per day > 40, use a Class III TF equation and design procedure.

FULL-DEPTH HMA PAVEMENT
DESIGN CALCULATIONS FOR LOCAL AGENCIES

Figure 37-4P

37-4.05 Example Calculations

Figure 37-4P provides a chart for design calculations.

* * * * *

Example 37-4.1

Given: Class I, 4-lane pavement
 Design Period: 20 years
 Design Traffic:
 ADT: 14,000
 86% PV (12,040), 8% SU (1,120), 6% MU (840)
 80,000 lb load limit
 Location: Lake County
 Design subgrade support rating: fair
 Posted speed limit: 30 mph (No Standing Traffic)

Problem: Design a full-depth HMA pavement for the given conditions.

Solution:

1. From Figure 37-4C use the TF equation for a 4-lane Class I pavement with an 80,000 lb load limit.

4 or 5 Lane Pavement (Rural and Urban):

$$TF = DP \frac{(0.047 PV) + (59.625 SU) + (217.139 MU)}{1,000,000}$$

$$TF = 20 \frac{(0.047 \times 12,040) + (59.625 \times 1,120) + (217.139 \times 840)}{1,000,000}$$

$$TF = 4.99$$

2. From Figure 37-4E, the binder grade should be PG 64-28, SBR PG 64-28, or SBS PG 64-28.
3. From Figure 37-4G the design pavement HMA temperature would be 76°F.
4. Use Figure 37-4I ($TF \geq 0.5$) in conjunction with the design TF of 4.99 to determine that the HMA design strain is 63 microstrain.
5. Use Figure 37-4J in conjunction with a design pavement HMA temperature of 76°F to determine that the HMA design modulus is 650 ksi for PG 64-28.

BUREAU OF LOCAL ROADS & STREETS

Jan 2006

PAVEMENT DESIGN

37-4(21)

6. Use Figure 37-4L (subgrade support rating is fair) in conjunction with the HMA strain of 63 microstrain and the design modulus of 650 ksi to determine a design HMA thickness of 12.25 in. This is the thickness after rounding to the next higher 0.25 in.
7. A 12 in improved subgrade is required for all Class I and II full-depth HMA projects unless built upon a granular subgrade.

Example 37-4.2

Given: Class II, two-lane pavement
Design Period: 20 years
Design Traffic:
ADT: 3000
95% PV (2850), 3% SU (90), 2% MU (60)
73,280 lb load limit
Location: Springfield, Sangamon County
The subgrade particle sizes are as follows:
20% Sand; 55% Silt; 25% Clay
Posted speed limit: 30 mph (with bus stops)

Problem: Design a full-depth HMA pavement for the given conditions.

Solution:

1. From Figure 37-4B use the TF equation for a 2-lane Class II pavement with a 73,280 lb load limit.

2 or 3 Lane Pavement:

$$TF = DP \frac{(0.073 PV) + (44.530 SU) + (156.403 MU)}{1,000,000}$$

$$TF = 20 \frac{(0.073 \times 2850) + (44.530 \times 90) + (156.403 \times 60)}{1,000,000}$$

$$TF = 0.27$$

2. From Figure 37-4E, the binder grade should be PG 76-22, SBR PG 76-22, or SBS PG 76-22. The bus stops will result in standing traffic.
3. Based on the subgrade particle sizes and Figure 37-6A, the subgrade support rating is poor.
4. From Figure 37-4G, the design pavement HMA temperature for Sangamon County would be 80.8°F.

BUREAU OF LOCAL ROADS & STREETS

37-4(22)

PAVEMENT DESIGN

Jan 2006

5. Use Figure 37-4H, TF is less than 0.5, in conjunction with the design TF of 0.27 to determine that the HMA design strain is 210 microstrain.
6. Use Figure 37-4J in conjunction with the design pavement HMA temperature of 80.8°F to determine that the HMA design modulus is 525 ksi for a PG 76-22.
7. Use Figure 37-4K, subgrade support rating is poor, in conjunction with the HMA strain of 210 microstrain and the design modulus of 525 ksi to determine a design HMA thickness of 6.50 in. This thickness is after rounding to the next higher 0.25 in.
8. A 12 in improved subgrade is required for all Class I and II full-depth HMA projects unless built upon a granular subgrade.

Example 37-4.3

Given: Class IV, 2-lane pavement
Design Period: 20 years
Design Traffic:
ADT: 350
90% PV (315), 6% SU (21), 4% MU (14)
73,280 lb. load limit
Location: Marion, Williamson County
Design subgrade support rating: poor
Asphalt Binder: PG 64-22
Fall construction is expected.

Problem: Design a full-depth HMA pavement for the given conditions.

Solution:

1. There are 35 HCV's per day (21 SU's + 14 MU's).
2. Because the pavement is a Class IV road with less than 40 HCV's per day, a minimum 6 in HMA pavement is required. A 12 in improved subgrade layer should be included as part of the design.

Note: A 12 in improved subgrade is optional for Class III and IV full-depth HMA projects. The subgrade still must satisfy the requirements of Section 37-7. In this case, due to the poor subgrade support rating and possible late fall construction with little chance of good drying weather, a 12 in improved subgrade layer should be included as part of the initial design. The improved subgrade layer requirement and pay items can be deleted by the resident engineer, Class III and IV pavements only, if deemed unnecessary at the time of construction.

* * * * *

37-5 COMPOSITE PAVEMENT DESIGN FOR LOCAL AGENCIES

37-5.01 Introduction

37-5.01(a) Design of Composite Pavements

A composite pavement is a pavement with a HMA surface layer over a Portland cement concrete (PCC) slab. Advantages of placing the HMA layer over the PCC slab include a reduced PCC slab thickness due to the structural contribution of the HMA, and a more uniform surface appearance in the event that pavement patches are used to repair utility cuts, or due to widening or otherwise modifying the existing pavement. The HMA surface layer also results in reduced thermal gradients through the PCC slab. These reduced thermal effects also allow for increased spacing between joints in the PCC slab.

Whitetopping, a thin PCC overlay over an existing HMA surfaced pavement, is a special design. Use of whitetopping requires a variance from the Central BLRS. If a variance is granted, the Central BLRS will provide assistance to the local agency to develop a design.

37-5.01(b) Usage of Procedure

The composite pavement design procedure may be used for new construction, reconstruction (removal and replacement using the same alignment), or add lanes.

A pavement design is not required when small quantities of pavement are to be constructed. Small quantities are defined as follows:

- less than one city block in length, or
- less than 3000 yd², or
- widening less than 1 lane width.

When small quantities are to be constructed adjacent to existing pavements, the designer should:

- duplicate the existing total pavement structure, or
- provide a structurally equivalent pavement, or
- design assuming a “poor” subgrade support rating.

Stage construction is the planned construction of the pavement structure in 2 or more stages. If stage construction of a composite pavement is planned for separate contracts, the designer should design the PCC slab thickness and joint spacing using the rigid pavement design procedure.

BUREAU OF LOCAL ROADS & STREETS

37-5(2)

PAVEMENT DESIGN

Jan 2006

37-5.02 Basic Design Elements**37-5.02(a) Minimum Material Requirements**

The Portland cement concrete must meet the requirements for Class PV concrete, as specified in the *IDOT Standard Specifications*. HMA binder and surface courses must be Superpave. Type A granular subbase, according to the requirements of the *IDOT Standard Specifications*, must be used where granular subbase is specified.

37-5.02(b) Class of Roads or Streets

The class of the road or street for which the pavement structural design is being determined is dependent upon the structural design traffic. These road classifications are defined in Section 37-1.

37-5.02(c) Design Period

The design period (DP) is the length of time in years that the pavement is being designed to serve the structural design traffic. For all classes of composite pavements, the minimum design period is 20 years.

37-5.02(d) Structural Design Traffic

The structural design traffic is the estimated ADT for the year representing one-half of the design period. For example, when the design period is 20 years, the structural design traffic will be an estimate of the ADT projected to 10 years after the construction date.

The structural design traffic is estimated from current traffic count data obtained either by visual counts or from traffic maps published by IDOT. If SU and MU counts are not available for Class III and IV roads and streets, an estimate of those counts may be made from the component percentages of the total traffic in Figure 37-5A.

Class of Road or Street	Percentage of Structural Design Traffic		
	PV (%)	SU (%)	MU (%)
III	88	7	5
IV	88	9	3

TRAFFIC PERCENTAGE (CLASS III AND IV)**Figure 37-5A**

37-5.02(e) Traffic Factors

For Class I, II, and III roads and streets, the design Traffic Factor (TF) for composite pavements is determined from the 73,280 lb and 80,000 lb load limit formulas shown in Figures 37-5B and 37-5C. The formulas shown are based on the statewide average distribution of vehicle types and axle loadings, which are directly applicable to most roads and streets. However, cases will arise in which a formula cannot be used, and a special analysis will be necessary (e.g., a highway adjacent to an industrial site with Heavy Commercial Vehicles (HCV's) entering and leaving the site generally traveling empty in one direction and fully loaded in the other). These cases should be referred to the Central BLRS for special analysis. It will be necessary for the local agency to provide the Central BLRS with the structural design traffic, the design period, and traffic distribution by PV, SU, and MU vehicles.

The TF equations in Figure 37-5C are provided to accommodate 80,000 lb trucks. In Illinois these larger and heavier trucks are permitted to use the Interstate system and a system of designated State routes. In addition, trucks operating on this system are allowed to have limited access to points of loading and unloading and facilities for food, fuel, repairs, and rest. Local authorities of roads and streets also have the authority to designate 80,000 lb truck routes. The pavement design procedure for 73,280 lb and 80,000 lb routes is the same except for the TF equations.

For Class IV composite pavements, a design TF is not necessary. A preadjusted PCC slab thickness of 6 in should be used for all Class IV composite pavements.

37-5.02(f) Transverse Pavement Joints

For composite pavements, use 20 ft transverse joint spacing. Use of joint spacing less than 20 ft does not significantly reduce the PCC slab thickness compared with bare PCC jointed pavements. Use of joint spacings in excess of 20 ft can result in intermediate cracking.

The volume of traffic the pavement will carry determines the type of load transfer device necessary to control faulting at the joints. Mechanical load transfer devices (e.g., dowel bars) are required on pavements that have a design TF of 3.0 or greater. For pavements with a TF less than 3.0, the designer has the option of using dowel bars or relying on aggregate interlock for load transfer.

Transverse joints in the PCC slab will result in reflective cracking in the HMA surface. Sawed and sealed joints in the HMA surface should be considered over all transverse PCC joints in order to facilitate future maintenance.

COMPOSITE PAVEMENT TRAFFIC FACTOR EQUATIONS (80,000 lb Load Limit)

Figure 37-5C

37-5.02(g) Subgrade

Roadbed soils that are susceptible to excessive volume changes, permanent deformation, excessive deflection and rebound, frost heave, and/or non-uniform support can affect pavement performance. For Class I and II roads, the designer is required to follow the guidelines found in Section 37-7. Use of Section 37-7 is optional for all Class III and IV roadways. In situ soils that do not develop an Immediate Bearing Value (IBV) in excess of 6.0 when compacted at, or wet of, optimum moisture content, require corrective action. The designer should recommend corrective actions (e.g., undercutting, moisture density control, modified soil layer) in the design plans and specifications.

Necessary corrective actions as required by Section 37-7 will be in addition to the subbase requirements of the pavement design.

37-5.02(h) Subgrade Support Rating

The general physical characteristics of the roadbed soil affect the design thickness and performance of the pavement structure. For pavement design purposes there are 3 subgrade support ratings (SSR) — poor, fair, and granular. The SSR is determined by using geotechnical grain size analysis and Figure 37-6A. The SSR should represent the average/majority classification within the design section. Figure 37-6A assumes a high water table and a frost penetration depth typical of an Illinois subgrade soil. For small projects, the SSR may be estimated by using USDA county soil reports or assumed to be “poor”. The pavement thickness design curves in Figure 37-5D are based on a fair SSR. Adjustments in the design thickness are made for the poor and granular subgrades.

37-5.02(i) Subbase

A subbase under a pavement serves two purposes. Initially it provides a stable construction platform for the base and surface courses. After construction it can improve the pavement performance by alleviating pumping of fine-grained soils and providing positive drainage for the pavement system. The usage and thickness requirements are shown in Figure 37-5E.

When placing a composite pavement directly over a flexible pavement with a HMA surface, consult with the Central BLRS for design assistance.

SLAB THICKNESS
(3 in HMA Surface on PCC Slab, Fair Subgrade)

Figure 37-5D

BUREAU OF LOCAL ROADS & STREETS
PAVEMENT DESIGN

Jan 2006

37-5(7)

Road Class	Subbase Material	Usage ⁽¹⁾	Minimum Thickness (in)
Class I & II	Stabilized Material	Required	4
Class III & IV	Granular ⁽²⁾ , T.F. ≥ 0.7	Required	4
	Granular ⁽²⁾ , T.F. < 0.7	Optional	4

Notes:

- Subbase is not required for urban sections having curbs and gutters and storm sewer systems. However, at the designer's option, a 4 in minimum subbase may be used to serve as a working platform where poor soil conditions exist.*
- Use Type A granular subbase according to the requirements of the IDOT Standard Specifications.*

SUBBASE REQUIREMENTS

Figure 37-5E

37-5.02(j) PG Binder Grade Selection

The PG binder grade can affect the performance of a HMA mixture. Rutting or permanent deformation of the HMA surface is a distress common to composite pavements. This design procedure assumes that HMA rutting is considered in the material selection and mixture design process. Because the binder grade can impact the ability of the mix to resist rutting, selection of the appropriate high temperature grade is important. Thermal cracking is not a failure mode for composite pavements, and so the lower temperature grade is not as critical. That is why PG XX-22 binders are specified for composite pavements rather than the PG XX-28 grades appropriate for full-depth HMA pavements, where thermal cracking is of concern.

Composite pavements should use the grades shown in Figures 37-5F and 37-5G. Areas of slow moving or standing traffic (e.g., intersections, bus stops, city streets) warrant the use of stiffer binders to resist rutting. These adjustments should be made according to Figures 37-5F and 37-5G for the corresponding N_{design} number, provided by the district, and/or design ESALs. The appropriate grade of binder should be reported on the plans.

Note that the PG binder grade selection tables for composite pavements for local agency pavement design differ from the tables used for the State system. A lower level of reliability is used for local agency design than for the State system.

The local agency must request a variance from Central BLRS to use a different PG binder than specified in Figure 37-5F and Figure 37-5G.

70	3 to < 10	PG 58-22	PG 64-22	PG 70-22, SBR PG 70-22 ⁽⁹⁾ , or SBS PG 70-22
90	10 to < 30	PG 58-22 ⁽⁸⁾	PG 64-22 ⁽⁸⁾	PG 70-22, SBR PG 70-22 ⁽⁹⁾ , or SBS PG 70-22
105	≥ 30	PG 64-22	PG 70-22, SBR PG 70-22 ⁽⁹⁾ , or SBS PG 70-22	SBR PG 76-22 ⁽⁹⁾ or SBS PG 76-22

Notes:

1. Design ESALs are the anticipated project traffic level expected on the design lane over a 20 year period. Regardless of the actual design life of the roadway, determine the design ESALs for 20 years and choose the appropriate N_{design} level. For N_{design} and PG binder grade selection purposes only, the design ESALs are calculated using the flexible traffic factor equations found in the full-depth pavement design procedure. Rigid traffic factors given in Figure 37-5B and Figure 37-5C are required for the composite pavement thickness design.
2. The binder grades provided in Figure 37-5F are based on the recommendations given in Illinois-Modified AASHTO MP-2, Table 1, "Binder Selection on the Basis of Traffic Speed and Traffic Level".
3. For mixtures containing a minimum of 15% RAP, the high temperature binder grade should be decreased by one grade equivalent. For example, if use of a PG 64-22 is specified for a virgin aggregate mix, a PG 58-22 should be used for a mix containing a minimum of 15% RAP. Mixtures containing less than 15% RAP should use the binder grade specified in Figure 37-5F.
4. Use these grades for composite pavements and all overlays
5. Standard traffic is used where the average traffic speed is greater than 43 mph (70 km/h).
6. Slow traffic is used where the average traffic speed ranges from 12 to 43 mph (20 to 70 km/h).
7. Standing traffic is used where the average traffic speed is less than 12 mph (20 km/h).
8. Give consideration to increasing the high temperature grade by one grade equivalent.
9. SBR modified binders are not available in Illinois at this time.

Notes:

1. Design ESALs are the anticipated project traffic level expected on the design lane over a 20 year period. Regardless of the actual design life of the roadway, determine the design ESALs for 20 years and choose the appropriate N_{design} level. For N_{design} and PG binder grade selection purposes only, the design ESALs are calculated using the flexible traffic factor equations found in the full-depth pavement design procedure. Rigid traffic factors given in Figure 37-5B and Figure 37-5C are required for the composite pavement thickness design.
2. The binder grades provided in Figure 37-5G are based on the recommendations given in Illinois-Modified AASHTO MP-2, Table 1, "Binder Selection on the Basis of Traffic Speed and Traffic Level."
3. For mixtures containing a minimum of 15% RAP, the high temperature binder grade should be decreased by one grade equivalent. For example, if use of a PG 64-22 is specified for a virgin aggregate mix, a PG 58-22 should be used for a mix containing a minimum of 15% RAP. Mixtures containing less than 15% RAP should use the binder grade specified in Figure 37-5G.
4. Use these grades for composite pavements and all overlays.
5. Standard traffic is used where the average traffic speed is greater than 43 mph (70 km/h).
6. Slow traffic is used where the average traffic speed ranges from 12 to 43 mph (20 to 70 km/h).
7. Standing traffic is used where the average traffic speed is less than 12 mph (20 km/h).
8. Consideration should be given to increasing the high temperature grade by one grade equivalent.
9. SBR modified binders are not available in Illinois at this time.

37-5.02(k) Design Reliability

Design reliability is taken into account through traffic multipliers applied to the design TF. These traffic multipliers are built into the PCC slab thickness design curves in Figure 37-5D. Figure 37-5D contains curves for both high and medium reliability levels. The minimum reliability levels by class of road are shown in 37-5H.

Road Class	Minimum Reliability Levels	Percent Reliability
Class I and II	High	90's
Class III & IV	Medium	70's and 80's

RELIABILITY LEVELS**Figure 37-5H****37-5.03 Thickness Design****37-5.03(a) Minimum Design Thickness**

Once all pavement thickness adjustments have been made, the minimum design must have at least:

2.0 in of HMA and 6.5 in of PCC, or
3.0 in of HMA and 6.0 in of PCC.

37-5.03(b) Preadjusted Slab Thickness

The composite thickness design procedure is based on determining the thickness of the preadjusted pavement assuming a fair SSR, 3 in of HMA surface, 20 ft joint spacing, and a flexible or untied PCC shoulder. Using the level of reliability specified in Figure 37-5H and the design TF, the PCC slab thickness is determined from the curves shown in Figure 37-5D. For Class IV pavements, the preadjusted slab thickness is 6 in. Adjustments to this basic slab thickness can be made for other factors (e.g., pavement support, shoulder type, overloads, and HMA thickness). Adjustments for pavement support conditions must be done prior to other adjustments. The final design thickness should be rounded to the next highest 0.25 in.

BUREAU OF LOCAL ROADS & STREETS

Jan 2006

PAVEMENT DESIGN

37-5(11)

37-5.03(c) Slab Thickness Adjustments

In determining any adjustments, consider the following:

1. Pavement Support. Pavement thickness adjustments are based on the subgrade rating and whether or not the pavement structure will have a subbase. The subgrade support adjustments factors are shown in Figure 37-5I.

Regardless of the decreases indicated in Figure 37-5I, provide a minimum PCC slab thickness for composite pavements of at least 6.0 in.

Subgrade Rating	Subbase Type	Slab Thickness Adjustment (in)
Poor	None	+ 0.25
Poor	Granular	No adjustment
Poor	Stabilized	- 0.25
Fair	None	No adjustment
Fair	Granular	- 0.25
Fair	Stabilized	- 0.25
Granular	None	- 0.25
Granular	Granular	- 0.25
Granular	Stabilized	- 0.25
	Existing Pavement	- 0.25

ADJUSTMENTS FOR PAVEMENT SUPPORT**Figure 37-5I**

2. Shoulder Type. With flexible or untied PCC shoulders, no adjustments are allowed. Adjustments for tied PCC shoulders, tied curb and gutter, integral curb and gutter, or widened outer lanes will be made according to Figure 37-5J. To receive the thickness reduction, the tied shoulders must be tied with a #6 or larger tie bar at 24 in spacing. A #6 or larger bar is required to ensure that load transfer is obtained between the pavement and the curb/shoulder. Designers may specify smaller tie bars, but in these cases, no deduction in pavement thickness will be allowed based on shoulder type.

Slab Thickness (in) after adjustment for support conditions	Slab Thickness Adjustment (in)
> 8.0	- 0.50
8.0 in to 7.0	- 0.375
< 7.0	No adjustment

ADJUSTMENTS FOR SHOULDER TYPE**Figure 37-5J**

BUREAU OF LOCAL ROADS & STREETS

37-5(12)

PAVEMENT DESIGN

Jan 2006

3. Overloads. Pavement overloads are those loads that are anticipated to exceed the load limits from which the design TF's were developed. These loads are typically created by permit loads and commercial, garbage, construction, and farm trucks, as well as buses and some farm implements. For those pavements for which a significant number of overloads can be anticipated, adjust the pavement thickness as shown in Figure 37-5K.

For pavements designed for a TF of 1.0 and higher, no thickness adjustment is necessary. Care must be taken, however, to ensure the TF selected for design accurately represents the anticipated traffic. A project adjacent to an industrial site with HCV's entering and exiting the site should be referred to the Central BLRS for special analysis.

Design TF	Average No. Overloads Per Week	Slab Thickness Adjustment (in)
≤ 0.50	5	+ 0.15
	10	+ 0.30
.50 to 0.75	5	+ 0.10
	10	+ 0.15
0.75 to 1.0	5	+ 0.05
	10	+ 0.10
> 1.0	5	No Adjustment
	10	No Adjustment

ADJUSTMENTS FOR OVERLOADS**Figure 37-5K**

4. HMA Surface Layer Thickness. The preadjusted slab thickness is based on a HMA surface layer of 3 in placed on the PCC slab. If the HMA layer thickness is other than 3 in, adjust the thickness using Figure 37-5L. In no case should the thickness of the HMA layer be less than 2 in or the PCC slab less than 6 in.

HMA Layer Thickness (in)	Thickness Adjustment for PCC Slab (in)
2	+ 0.50
2.5	+ 0.25
3	No adjustment
4	- 0.25
5	- 0.50

ADJUSTMENTS FOR HMA THICKNESS
Figure 37-5L

37-5.03(d) Dowel Bars

Dowel bars must be used in all pavements with a TF of 3.0 or greater. Dowel bar diameter requirements are given in Figure 37-5M.

Normal dowel spacing is 12 in; however, with approval from the Central BLRS, the dowels can be clustered in the wheel paths. There are no adjustments in pavement thickness when doweled joints are used.

Slab Thickness (in)	Dowel Diameter (in)
≥ 8.00	1.50
7.00 to 7.99	1.25
< 7.00	1.00

DOWEL DIAMETER

37-5.04 Example Calculation

* * * * *

Example 37-5.1

Given: Class I, one-way urban street
 Design period: 20 years
 Design Traffic:
 ADT: 8900
 94% PV (8366), 5% SU (445), 1% MU (89)
 73,280 lb load limit
 Subgrade Support Rating: poor
 Shoulders: tied curb and gutter
 Overloaded vehicles: 5 per week
 3 in HMA surface
 Ndesign level: 50
 District 6, Slow Traffic

Problem: Design a composite pavement for the given conditions.

Solution:

1. Use Figure 37-5B and determine the TF equation for a one-way Class I pavement with a 73,280 lb load limit.

One-way Streets and Pavements (Rural and Urban)

$$TF = DP \frac{((0.073 \text{ PV}) + (58.035 \text{ SU}) + (274.665 \text{ MU}))}{1,000,000}$$

$$TF = 20 \left[\frac{(0.073 \times 8366) + (58.035 \times 445) + (274.665 \times 89)}{1,000,000} \right]$$

$$TF = 1.02$$

2. Because the pavement is a Class I facility, a high design reliability is required; see Figure 37-5H. A subbase is optional; see Note #1 in Figure 37-5E. For this example, assume a 4 in stabilized subbase is used. According to Section 37-5.02(f), if the TF is less than 3.0, the designer may choose either dowels or aggregate interlock for load transfer.
3. From Figure 37-5D, the slab thickness required for high reliability, fair subgrade support, and flexible shoulders is 7.0 in, with a 3 in HMA overlay. From this thickness adjustments can be made for pavement support, shoulder type, overloads, and HMA thickness.

BUREAU OF LOCAL ROADS & STREETS
PAVEMENT DESIGN

37-5(18)

Jan 2006

- Basic slab thickness (from Figure 37-5D): 7 in
- Adjustment for poor subgrade with stabilized subbase (Figure 37-5I): -0.25 in
- Slab thickness adjusted for support conditions: 6.75 in*
- Adjustment for tied curb and gutter with slab less than 7 in (Figure 37-5J): no adjustment
- Adjustment for overloads with TF of 1.02 (Figure 37-5K): no adjustment
- Adjustment for 3 in HMA surface (Figure 37-5L): no adjustment
- Final thickness: 6.75 in

**All other adjustments are made on slab thickness after adjustment for support conditions.*

4. Alternative designs may be made by varying the HMA surface thickness. See Figure 37-5L. For example, another possible design could be a 7 in PCC slab with 2.5 in of HMA surface.
5. Based on Figure 37-5G, a PG 64-22 binder should be used, assuming slow traffic, with average traffic speeds from 12 to 43 mph, although consideration should be given to specifying a PG 70-22, SBR PG 70-22, or SBS PG 70-22.

37-6 SUBGRADE INPUTS FOR LOCAL ROAD PAVEMENT DESIGN

37-6.01 Introduction

The variability of insitu subgrade strengths can be quite large. Subgrade strength can vary with depth, distance along the roadway, or location across the pavement width. Knowledge of the soil present on the section of roadway being designed is essential to produce a satisfactory design. Flexible and rigid pavement designs require different subgrade design inputs.

37-6.01(a) Full-Depth Asphalt Concrete, Jointed PCC, and Composite Pavements

A Subgrade Support Rating (SSR) is used as the design subgrade input for full-depth HMA, jointed PCC, and composite pavement designs. The SSR is based on a grain size analysis of the subgrade soil. Figure 37-6A is a graphical method to determine the SSR (poor, fair, or granular) based on the percentage of clay, silt, and sand in the subgrade soil.

37-6.01(b) Flexible Pavement Design

The procedures discussed in this Section do not apply to full-depth HMA pavements.

The majority of soils found in Illinois are fine-grained soils. The subgrade resilient modulus (E_{Ri}) is used as the design subgrade input for all flexible pavement designs except full-depth HMA. The E_{Ri} is an indicator of a soil's resilient behavior under loadings. Springtime E_{Ri} , which reflects high-moisture content and a thaw-weakened condition, is used for design purposes. Design E_{Ri} values can be obtained through field testing or laboratory testing, or estimated from soil property or strength data. The County Soil Report, prepared by the U.S. Department of Agriculture (USDA) Natural Resource Conservation Service, can be an excellent source of information. The County Soil Report includes a soil report map and listings of engineering index properties and physical and chemical properties of the soils. The data are listed by soil series, which have similar profile features and characteristics wherever they are located.

To determine the subgrade resilient modulus, use the following procedures:

1. Preliminary E_{Ri} Determination. Listed below are 5 methods to determine preliminary E_{Ri} values, which are later adjusted for moisture. The methods vary in complexity from requiring field or laboratory tests to using county soil maps. The most accurate methods appear first in the listing. The results are acceptable in all cases, but are more accurate and reliable for the method involving field or laboratory tests. The 5 methods are described below:

**SUBGRADE SUPPORT RATING (SSR)****Figure 37-6A**

BUREAU OF LOCAL ROADS & STREETS
PAVEMENT DESIGN

Jan 2006

37-6(3)

- a. Resilient Modulus Testing. The E_{Ri} of a soil may be determined by performing repeated unconfined compression testing in the laboratory. Subgrade specimens from insitu soil or laboratory-prepared specimens may be tested. Laboratory prepared specimens with a range of moisture contents and densities can be tested to simulate the variable conditions found in the field. The Central BLRS may be contacted for additional information regarding a resilient modulus testing format.
- b. Falling Weight Deflectometer (FWD) Testing. Design E_{Ri} values can be back calculated from FWD data taken from existing pavements. County soil maps can be used to identify the major soil series found in an area. A FWD testing scheme that targets existing typical flexible pavements constructed in the major soil series of the area can be developed using this information. A county-wide FWD testing program that provides comprehensive coverage can be completed in 3 to 5 days in most cases. Springtime FWD testing is preferred, but a seasonal adjustment factor may be applied to the back calculated E_{Ri} if the FWD testing is conducted during other seasons. Contact the Central BLRS if a seasonal adjustment factor is required. The average E_{Ri} back calculated from FWD testing should be used as the design E_{Ri} .

Design E_{Ri} values may be obtained from FWD testing in a cost-effective manner. Back calculated E_{Ri} values do not represent a single point location, but reflect the composite influence of a large volume of insitu soil, including the different soil horizons.

- c. Estimating E_{Ri} from Strength Data. An E_{Ri} value can be estimated from strength data obtained with a Corps of Engineers hand-held cone penetrometer, or a dynamic cone penetrometer (DCP). Both the Corps of Engineers hand-held cone penetrometer and the DCP are field-testing devices used to rapidly evaluate the insitu strength of fine-grained and granular soils and granular base and subbase materials. The Corps of Engineers hand-held cone penetrometer is limited to an 18 in depth of penetration and a maximum load of 150 lbs (IBV = 7.5). Data obtained from Corps of Engineers hand-held cone penetrometer and DCP testing can be used to estimate the IBV and E_{Ri} through the following equations:

$$IBV = \frac{CI}{40} \quad \text{Equation 37-6.1}$$

Where: IBV = Immediate Bearing Value
 CI = Corps of Engineers Cone Index, psi

$$\text{LOG IBV} = 0.84 - 1.26 \text{ LOG (PR)} \quad \text{Equation 37-6.2}$$

Where: IBV = Immediate Bearing Value
 PR = DCP penetration rate, in/blow

$$Q_u = 4.5 \text{ IBV} \quad \text{Equation 37-6.3}$$

Where: Q_u = Unconfined compressive strength, psi
 IBV = Immediate Bearing Value

$$E_{Ri}^* = 0.86 + 0.307 Q_u \quad \text{Equation 37-6.4}$$

Where: E_{Ri}^* = Subgrade resilient modulus, ksi
 Q_u = Unconfined compressive strength, psi

*Moisture adjustment is necessary.

An E_{Ri} can be established with Corps of Engineers cone penetrometer or DCP testing at the project site or on existing flexible pavement sections constructed on the same soil series as the roadway being designed. Ideally, this testing should be conducted during the spring. If testing is not conducted during the spring, the E_{Ri} value calculated from Equation 37-6.4 will need to be corrected as discussed in Section 37-6.01(b).

- d. Estimating E_{Ri} from Soil Properties. Design E_{Ri} values can be estimated based on a soil's clay content (< 2 micron) and plasticity index (PI). These values are easily obtainable from an analysis of the project's soils or the County Soil Report. Equation 37-6.5 may be used to predict E_{Ri} at optimum water content and 95% AASHTO T-99 maximum dry density:

$$E_{Ri}(\text{OPT})^* = 4.46 + 0.098 (\% \text{ Clay}) + 0.119 (\text{PI}) \quad \text{Equation 37-6.5}$$

Where: $E_{Ri}(\text{OPT})^*$ = E_{Ri} at optimum moisture content and 95% of AASHTO T-99 maximum dry density, ksi
 $\% \text{ Clay}$ = Clay content (<2 microns), %
 PI = Plastic Index

* Moisture adjustment is necessary.

Figure 37-6B is a graphical solution to Equation 37-6.5. If the County Soil Report is used to estimate the soil's clay content and PI, the designer should use the midpoint of clay content and PI values given.

- e. Typical E_{Ri} Values. If data are not available to estimate E_{Ri} values using the previously discussed methods, Figures 37-6C or 37-6D may be used to estimate typical E_{Ri} values. If the water table and frost penetration levels are known, Figure 37-6C may be used to determine typical E_{Ri} values based on the AASHTO soil classification system.

If the frost penetration and water table levels are not known, the designer may use Figure 37-6D to estimate a typical E_{Ri} value. These E_{Ri} values were developed from resilient modulus testing of fine-grained Illinois soils, represent 95% of AASHTO T-99 maximum dry density and moisture contents 2% wet of optimum.

PAVEMENT DESIGN

37-6(7)

2. Moisture Adjustment Procedure. The preliminary E_{Ri} determined by one of the above procedures (except for the resilient modulus laboratory or FWD methods) should be corrected to reflect the insitu moisture present under springtime conditions, if the test data reflects conditions other than those of a normal spring. The following procedure will apply:

- a. Known MDD and OMC. If the AASHTO T-99 maximum dry density (MDD), the optimum moisture content (OMC), and the specific gravity of soil solids (G_s) are known, Equation 37-6.6 can be used to calculate the moisture content for a given degree of saturation and 95% compaction.

$$MC_{\%SR} = \left[\frac{65.7}{MDD} - \frac{1}{G_s} \right] SR \quad \text{Equation 37-6.6}$$

Where: $MC_{\%SR}$ = Moisture content for a given degree of saturation, %
 MDD = AASHTO T-99 maximum dry density, pcf
 G_s = Specific gravity of soil solids
 SR = Degree of Saturation, % *

- * For very poorly, poorly, and imperfectly drained soils, the E_{Ri} estimate should be adjusted to a 100% SR. All other drainage classes should be adjusted to a 90% SR. The drainage classification for a soil series can be found in the County Soil Report.

- b. Unknown MDD and OMC. If the MDD and OMC have not been determined, they can be estimated using Equations 37-6.7 and 37-6.8 and then used to solve Equation 37-6.6.

$$OMC = 1.86 + 0.499 (LL) - 0.354 (PI) + 0.044 (P_{200}) \quad \text{Equation 37-6.7}$$

$$MDD = 138.96 - 1.10 (LL) + 0.796 (PI) - 0.062(P_{200}) \quad \text{Equation 37-6.8}$$

Where: OMC = Optimum moisture content, %
 LL = Liquid limit, %*
 PI = Plasticity index *
 P_{200} = Percent passing #200 sieve *

- * These inputs can be obtained from laboratory testing or selected from the midpoint of the range of values presented for the given soil series in the County Soil Report.

- c. Adjustment. Once the moisture content for the required degree of saturation is calculated, the field moisture adjustment and design E_{Ri} can be calculated.

$$FMA = MC_{\%SR} - OMC \quad \text{Equation 37-6.9}$$

Where: FMA = Field moisture adjustment, %
 $MC_{\%SR}$ = Moisture content for a given degree of saturation, %
 OMC = Optimum moisture content, %

$$\text{Design } E_{Ri} = E_{Ri} (\text{OPT}) - ((\text{FMA})(\text{MAF})) \quad \text{Equation 37-6.10}$$

Where: Design E_{Ri} = E_{Ri} for flexible pavement design, corrected for insitu moisture conditions, ksi
 E_{Ri} (OPT) = E_{Ri} at OMC and 95% of MDD, ksi
 FMA = Field moisture adjustment, %
 MAF = Moisture adjustment factor, E_{Ri} decrease per 1% moisture increase, ksi/% *

* MAF is selected from Figure 37-6E based on USDA soil textural classification.

USDA Textural Classification	E_{Ri} Decrease/1% Moisture Increase (ksi/%)
Clay, Silty Clay, Silty Clay Loam, Clay Loam, Sandy Clay*, Sandy Clay Loam*	0.7
Silt Loam, Sandy Loam	1.5
Loam, Silt	2.1

* Estimated

E_{Ri} MOISTURE ADJUSTMENT FACTORS BASED ON USDA TEXTURAL CLASSIFICATION

Figure 37-6E

- d. Minimum Design E_{Ri} Values. A design E_{Ri} of 2 ksi is the lowest allowable design E_{Ri} . If the design E_{Ri} value calculated from Equation 37-6.10 is less than 2 ksi or does not reasonably compare with historical data for the soil series, other means for determining design E_{Ri} should be investigated. Soft subgrades with low E_{Ri} or IBV values may require remedial subgrade treatments as outlined in Section 37-7. Engineering judgment may also be required to decrease the design E_{Ri} to account for the effect of freeze-thaw cycles on the insitu springtime design condition.
3. Composite E_{Ri} Estimate. A soil profile (vertical sections) contains distinct soil layers, called horizons. The County Soil Report contains thicknesses and properties for each horizon in the soil series. In a typical flexible pavement, approximately 70% to 75% of the subgrade deflection occurs in the upper 60 in of the subgrade. For this reason, a composite E_{Ri} which considers the contributing effect of the E_{Ri} values of the different soil horizons in the 60 in zone should be calculated using Equation 37-6.11.

E_{Ri} values determined from FWD testing reflect the composite E_{Ri} value of the subgrade; therefore, no further adjustment for composite influences should be made.

BUREAU OF LOCAL ROADS & STREETS
PAVEMENT DESIGN

Jan 2006

37-6(9)

$$\text{Design Composite } E_{Ri} \text{ (ksi)} = \sum_{i=1}^n (F_i)(T_i)(E_i) \quad \text{Equation 37-6.11}$$

Where: i = Layer designator; $i = 1$ for the top layer
 n = Number of layers

DEFLECTION COEFFICIENTS AS A FUNCTION OF DEPTH

Figure 37-6F

37-6.02 Subgrade Design Input Examples

37-6.02(a) Grain Size Analysis

A grain size analysis shows that the subgrade soil contains 43% clay, 48% silt, and 9% sand. From Figure 37-6A, the Subgrade Support Rating (SSR) is FAIR. An SSR value is necessary for rigid and full-depth HMA pavement design procedures.

37-6.02(b) Resilient Modulus (E_{Ri}) From Laboratory Testing

Repeated compression testing in the laboratory is performed on subgrade specimens from insitu soil sampled during the spring or on laboratory-prepared specimens. The results should be adjusted to reflect the composite influence of the soil layers. If the soil samples were not taken during the spring, moisture adjustment factors would need to be applied prior to correcting for the composite influence of the soil layers.

37-6.02(c) Estimating E_{Ri} from Strength Data

A DCP was used to evaluate the insitu strength of a subgrade soil. Average DCP penetration rates for the soil are given in Figure 37-6G. IBV, Q_u , and E_{Ri} were calculated using Equations 37-6.2, 37-6.3, and 37-6.4, respectively.

37-6.02(d) Estimating E_{Ri} from Soil Properties

The roadway being designed passes through the MIAMI soil series. From the County Soil Report, the information shown in Figure 37-6H is obtained.

Soil Series	USDA Textural Class	Depth from Top of Subgrade, (in)	Clay (%)	PI	Liquid Limit	Percent Passing #200 Sieve
MIAMI*	Clay Loam, Silty Clay Loam	0 – 16	25 – 35	17 – 31	35 – 50	64 – 95
	Loam, Clay Loam, Sandy Loam	16 – 60	15 – 28	2 – 20	20 – 40	50 – 64

* Assumes that A horizon material has been stripped; remaining material is representative of B and C horizons.

ESTIMATING FROM SOIL PROPERTIES

Figure 37-6H

From Equation 37-6.5, E_{Ri} (OPT) is calculated for each of the two depths using the midpoint values from the County Soil Report:

BUREAU OF LOCAL ROADS & STREETS

Jan 2006

PAVEMENT DESIGN

37-6(11)

$$\begin{aligned} 0 \text{ in} - 16 \text{ in: } E_{Ri} (\text{OPT}) &= 4.46 + 0.098 (30) + 0.119 (24) \\ E_{Ri} (\text{OPT}) &= 10.2 \text{ ksi} \end{aligned}$$

$$\begin{aligned} 16 \text{ in} - 60 \text{ in: } E_{Ri} (\text{OPT}) &= 4.46 + 0.098 (22) + 0.119 (11) \\ E_{Ri} (\text{OPT}) &= 7.9 \text{ ksi} \end{aligned}$$

These values must be corrected to reflect the springtime design condition. Figure 37-6I summarizes the moisture adjustment procedure.

Depth (in)	$E_{Ri} (\text{OPT})^{(1)}$ (ksi)	Optimum Moisture Content ⁽²⁾ (%)	Maximum Dry Density ⁽³⁾ (PCF)	Moisture Content for Given Saturation ⁽⁴⁾ (%)	Field Moisture Adjustment ⁽⁵⁾ (%)	Moisture Adjustment Factor ⁽⁶⁾	Design $E_{Ri}^{(7)}$ (ksi)
0 – 16	10.2	17.8	106.9	21.7	3.9	0.7	7.6
16 – 60	7.9	15.4	111.2	19.6	4.2	1.5	1.6(2.0) ⁽⁸⁾

Notes:

1. From Equation 37-6.5; use midpoint range values from the County Soil Report.
2. From Equation 37-6.7; use midpoint range values from the County Soil Report.
3. From Equation 37-6.8; use midpoint range values from the County Soil Report.
4. From Equation 37-6.6; degree of saturation equals 90%, because Miami soil series is well-drained; estimate G_s as 2.68.
5. From Equation 37-6.9.
6. From Figure 37-6E.
7. From Equation 37-6.10.
8. 2.0 ksi is the lowest allowable design E_{Ri} .

MOISTURE ADJUSTMENT PROCEDURE, SPRINGTIME DESIGN CONDITION

Figure 37-6I

The design E_{Ri} values adjusted to reflect springtime design conditions in Figure 37-6I must be combined into a composite E_{Ri} that considers the effect of the 60 in. zone under the load. This can be accomplished using Equation 37-6.11 and Figure 37-6F.

$$\begin{aligned} \text{Design Composite } E_{Ri} &= (0.038)(12)(7.6) + (0.015)(4)(7.6) + (0.015)(8)(2.0) + (0.008)(12)(2.0) \\ &\quad (0.011)(24)(2.0) = 4.9 \text{ ksi} \end{aligned}$$

37-6.02(e) Typical E_{Ri} Values

From the County Soil Report, the depth and USDA textural and AASHTO classification data are shown in Figure 37-6J. Average E_{Ri} values based on soil classification are shown.

Average E_{Ri} values calculated using Methods A and B need to be corrected for springtime testing conditions, if necessary, and the composite influence of the soil layers. Average E_{Ri} values calculated with Method C reflect springtime testing conditions, but still need to be adjusted to reflect the composite influence of the soil layers.

Soil Series	Depth (in)	USDA Textural Class	AASHTO Class	Average E_{Ri} (ksi) ⁽¹⁾		Average E_{Ri} (ksi) Springtime Conditions
				A	B	C
Tama ⁽²⁾	0 – 35	Silty Clay Loam	A-7	7.3	6.3	2.0
	35 – 60	Silty Clay Loam, Silt Loam	A-6	7.3	5.6	2.0

Notes:

1. 95% of AASHTO T-99 Maximum Dry Density and Moisture Contents 2% Wet of Optimum.
2. Assumes that A horizon has been stripped; remaining material is representative of the B and C horizons.
 - A. From Figure 37-6D, based on USDA textural class.
 - B. From Figure 37-6D, based on AASHTO class.
 - C. From Figure 37-6C, assuming high-water table and frost penetration.

AVERAGE E_{Ri} VALUES BASED ON SOIL CLASSIFICATION

37-7 SUBGRADE STABILITY REQUIREMENTS FOR LOCAL ROADS

37-7.01 Introduction

This is a condensation of *IDOT's Subgrade Stability Requirements for Local Roads Manual* and has been prepared to give the designer guidance on identifying and treating unsuitable subgrade material. The designer is required to use it for all Class I and II roadways. Its use is optional for all Class III and IV roadways.

Subgrade stability plays a critical role in the construction and performance of a pavement. A pavement's performance is directly related to the physical properties of the roadbed soils as well as the materials used in the pavement structure. Subgrade stability is a function of a soil's strength and its behavior under repeated loading. Both properties significantly influence pavement construction operations and the long-term performance of the subgrade. The subgrade should be sufficiently stable to:

- prevent excessive rutting and shoving during construction,
- provide good support for placement and compaction of pavement layers,
- limit pavement resilient (rebound) deflections to acceptable limits, and

restrict the development of excessive permanent deformation accumulation (rutting) in the subgrade during the service life of the pavement.

While the effect of less satisfactory soils can be reduced by increasing the thickness of the pavement structure, it may be necessary to take other steps to ensure adequate support for the operation of construction equipment and placement and compaction of the pavement layers.

37-7.02 Subgrade Stability Procedures

Many typical fine-grained Illinois soils do not develop an Immediate Bearing Value (IBV) in excess of 6.0 when compacted at, or wet of, optimum moisture content. Therefore, the designer must use one of the remedial procedures listed below when the insitu soil does not develop an IBV in excess of 6.0:

- undercut and backfill,
- modified soil layer, or
- moisture-density control.

Moisture-density control is the least permanent remedial procedure.

For pavement design purposes, use the insitu IBV prior to the remedial subgrade treatment.

Insitu IBV may be determined by use of a Corps of Engineers hand-held cone penetrometer, or a dynamic cone penetrometer (DCP). Correlations relating Corps of Engineers cone

BUREAU OF LOCAL ROADS & STREETS

37-7(2)

PAVEMENT DESIGN

Jan 2006

penetrometer and DCP test results to IBV values are summarized in Figure 37-7A. Central BLRS can be contacted for additional help in determining a field IBV value.

Static Cone Penetrometer	Dynamic Cone Penetrometer	Equivalent IBV
Corps of Engineers Cone Index (psi) ⁽¹⁾	DCP Penetration Rate (in/blow) ⁽²⁾	
40	4.6	1
80	2.7	2
120	1.9	3
160	1.5	4
200	1.3	5
240	1.1	6
280	1.0	7
320	0.9	8
360	0.8	9

Notes:

1. $IBV = \frac{\text{Cone Index}}{40}, \text{ psi}$
2. $LOG IBV = 0.84 - 1.26 LOG (\text{Penetration Rate, in /blow})$

SUBGRADE STRENGTH RELATIONSHIPS**Figure 37-7A****37-7.02(a) Undercut and Backfill**

Undercut and backfill involves removing the soft subgrade to a predetermined depth below the grade line and replacing it with granular material. This option is appropriate for localized area base repairs as well as for new construction. The granular material helps distribute the load over the unstable subgrade and serves as a working platform for construction equipment. The required removal and backfill depth can be determined from Figure 37-7B. The use of granular material with good shear strength is recommended. Factors that increase shear strength of a granular material are:

- using crushed materials;
- increasing top size;
- using well-graded materials, as opposed to one-size gradations;
- reducing PI of fines; and
- lowering fine content.

A geosynthetic may be used between the subgrade and the granular material to keep the subgrade layer separate from the granular layer, thereby, reducing the required granular thickness. Central BLRS should be contacted for assistance in designing the appropriate granular thickness when geosynthetics are used.

IBV-BASED THICKNESS DESIGN FOR UNDERCUT AND BACKFILL AND
MODIFIED SOIL LAYER REMEDIAL PROCEDURES

Figure 37-7B

37-7.02(b) Soil Modification

Unstable subgrades may be modified (Special Provision “Soil Modification”) to improve subgrade stability for new construction or large reconstruction projects. The thickness requirements shown in Figure 37-7B for granular backfill may also be used to determine the thickness of the modified soil layer.

If the soil is to be modified with lime, it is necessary to perform laboratory tests according to the department’s “Laboratory Evaluation/Design Procedure for Lime Stabilized Soil Mixtures” to determine if the soil is reactive and to determine the percentage of lime necessary for the soil to develop a minimum IBV of 10.0. The design commonly requires 0.5% percent more lime than the laboratory tests indicate to account for variables in the field.

If the IBV of the modified soil layer is less than 10.0, the engineer has the option of allowing the modified soil layer to field cure in an attempt to obtain an IBV of 10.0, per the department’s “Laboratory Evaluation/Design Procedure for Soil Modification”. If an IBV of 10.0 is not attainable with a field cure, or if the engineer decides not to wait for a field cure, addition of a granular layer will be required. Undercutting may be necessary prior to placing the granular layer in cases of grade restrictions. The thickness of the granular layer and the modified soil layer can be combined to meet the required thickness shown in Figure 37-7B. The minimum granular layer thickness should be 4 in. The minimum modified soil layer should be 10 in. Thickness adjustments may be modified to fit field conditions.

The modified soil layer should be covered with the subsequent pavement layer within the same construction season.

37-7.02(c) Moisture-Density Control

A soil wet of its optimum moisture content may not provide adequate subgrade stability when compacted to 95% of the standard laboratory density, as required by current IDOT specifications. Moisture controls as well as density controls may be required to ensure the proper compaction necessary to obtain a stable subgrade. Quantitative values of permissible compaction moisture content can be added to the compaction specifications to accomplish this. Laboratory testing, according to AASHTO T99, is required to determine appropriate compaction densities and moisture contents.

Draining the grade and drying the top portion of the subgrade by disking or tilling may control excess moisture at the time of construction, but it may be difficult to maintain that moisture condition throughout the pavement’s life.

37-7.03 Treatment Guidelines

The designer should use the following guidelines to determine which of the three remedial treatments is appropriate:

Specific details for each subgrade stability alternative should be determined. The required depth of undercut and backfill; the modifier percentage and layer thickness required; and the moisture and density levels required to achieve the needed stability levels should be determined.

The alternative procedures should be compared by considering construction variability, economics, permanence of treatment, and pavement performance benefits.

The best option should be selected.

More detailed information regarding subgrade stability requirements for local agency pavement design is detailed in *IDOT's Subgrade Stability Manual*.

37-7.04 Subgrade Stability Example

* * * * *

Example 37-7.1

Problem: Determine the subgrade treatment alternatives for a soil having an insitu IBV of 4.

Solution:

1. Requirements. Based on Figure 37-7B and an IBV of 4, remedial procedures are required.
2. Treatments. The three alternative treatments available are listed below along with specific requirements:
 - a. Undercut and Backfill. From Figure 37-7B, 11.5 in of granular material is required.
 - b. Modified Soil Layer. Figure 37-7B shows that 11.5 in of a modified soil layer would be required. If the immediate IBV of the modified soil layer obtained in the field is less than 10.0, the following options are available to the engineer:
 - field-cure the modified soil layer until an IBV of 10.0 is achieved; or
 - full- or partial-depth removal and replacement with granular material. In this case, a minimum thickness of 10 in of a modified soil layer and a minimum thickness of 4 in of granular material would be suitable.
 - c. Moisture-Density Control. Moisture and density specifications can be added to the contract documents to control compactive efforts, thereby assisting in obtaining a stable subgrade. Laboratory testing can determine the appropriate compaction densities and moisture contents. Disking or tilling may be necessary to control excess moisture.

BUREAU OF LOCAL ROADS & STREETS

37-7(6)

PAVEMENT DESIGN

Jan 2006

3. Comparison. The designer should consider the feasibility of these three options, their relative cost, contract time frame, and construction season. The best option should be selected and specified in the project plans. The designer should still use the insitu IBV for pavement design purposes rather than the IBV after remedial treatment.

* * * * *

37-8 HMA OVERLAYS

37-8.01 Introduction

HMA overlays are used to correct functional and structural deficiencies. Existing pavement conditions and estimates of future traffic dictate the thicknesses of these overlays.

Functional deficiency arises from any conditions that adversely affect the highway user. These include poor surface friction and texture, hydroplaning and splash from wheel path rutting, and excessive weathering, raveling, and block cracking.

Structural deficiency arises from any conditions that adversely affect the load-carrying capability of the pavement structure. These include inadequate thickness, loss of base or subgrade support, and moisture damage. It should be noted that several types of distress (e.g., distresses caused by poor construction techniques, low temperature cracking, base failure) are not initially caused by traffic loads but do become more severe under traffic to the point that they also detract from the load-carrying capability of the pavement.

It is important that the designer consider the type of deterioration present when determining whether the pavement has functional or structural deficiencies. For pavements with adequate existing structure, the overlay thickness is the thickness needed to correct the functional problem. Pavements that are structurally deficient require an overlay designed to upgrade the structural capacity.

37-8.02 Evaluation of Structures Being Resurfaced

All structures greater than 20.0 feet (6.1 m) in length within the limits of a resurfacing project that are not gapped should be evaluated for structural adequacy with the proposed resurfacing. This includes structures with zero increase in surfacing depth, such as those involving removal of surfacing with replacement with of equal thickness. These structures should be evaluated for structural adequacy and submitted to the Bureau of Bridges and Structures (BBS) for approval during the preliminary design phase. All structure condition ratings of these structures must be a "5" or greater. For such structures that are not being gapped, a Form BLR 10220 "Asbestos Determination Certification" will be required. The BBS will evaluate the adequacy of the structure, and record the status of the asbestos Form BLR 10220, before approval.

37-8.03 Reflective Crack Control

On pavements where existing cracks may propagate as reflective cracks, a reflective crack control treatment should be performed prior to the application of the HMA overlay. Such treatment should incorporate approved materials and follow recommended construction practices. Figure 37-8A summarizes the use of reflective crack control treatments.

BUREAU OF LOCAL ROADS & STREETS

37-8(2)

PAVEMENT DESIGN

Aug 2006

3. **Materials.** The following materials have been developed for the control of reflective cracking in HMA overlays. Complete specifications are included in the *Standard Specifications for Road and Bridge Construction*.
 - a. System A: Non-woven plastic reinforcing fabric.
 - b. System B: High strength fabric embedded in a layer of self-adhesive plasticized bitumen.
 - c. System C: Asphalt rubber membrane interlayer
4. **Applications.** Reflective crack control treatments are classified into two types of applications. Complete specifications are included the *Standard Specifications for Road and Bridge Construction*.
 - a. Strip Treatment – Suitable for use on rigid or flexible bases and should be considered for all projects that involve resurfacing of proposed or existing widening joints or where longitudinal reflective cracks would conflict with final traffic control markings thus causing confusion to the motorist. The pavement/paved shoulder joint should only be considered if tied with an effective load-transfer device.
 - b. Area Treatment – Suitable for use only on flexible bases. System B should not be used for area reflective crack control treatment.

Type of Treatment	Flexible Base	Rigid Base
Strip	System A, B, or C	System A, B, or C
Area	System A or C	Not Approved

USE OF REFLECTIVE CRACK CONTROL TREATMENTS
Figure 37-8A

37-8.04 Minimum Lift Thickness

All HMA surface and binder lifts must comply with three times nominal maximum aggregate size (3X NMAS) requirements in Section 37-1.03.

37-8.05 HMA Overlay Thickness – Existing Structural Level

The following policies address applying a HMA overlay over an existing rigid or flexible base. If a structural upgrade (i.e., 80,000 pound truck route) is desired, the design procedures in Section 37-8.06 must be used.

37-8.05(a) Local Agency Pavement Preservation (LAPP)

LAPP projects are intended to provide an “interim” improvement until a rehabilitation or reconstruction improvement can be funded. See Section 33-4 for more details.

37-8.05(b) Special Maintenance

Special maintenance projects are intended to provide HMA overlay on existing facility that has been performing adequately. Special maintenance projects are not eligible for federal funding. See Section 33-5 for more details.

37-8.05(c) Local Agency Policy Resurfacing Program

Local agency policy resurfacing program projects are intended to provide a minimum HMA overlay thicknesses for local agency projects. These projects must comply with the geometric criteria contained in Chapter 33.

If the existing pavements are performing adequately and show no real distress, the minimum thickness of a HMA overlay is provided in Figure 37-8C.

Typically resurfacing thickness for HMA overlays should be 3.50 in. This will allow for a 2.25 in binder course and a 1.25 in surface course. However, the final thickness will be selected by the engineer.

Type of Existing Pavement	Minimum HMA Overlay Thickness (in) ⁽¹⁾
Rigid (with good crown and contour)	2.50
Rigid (with poor crown and contour)	2.00 ⁽²⁾
Brick	2.00 ⁽²⁾
Flexible (HMA, Cold Mix, or Surface Treatments)	1.25 ⁽²⁾⁽³⁾

Notes:

- 1. All lifts must comply with the 3XNMAAS requirements in Section 37-1.03.*
- 2. Leveling binder should be used to fill any depressions and provide an adequate cross section.*
- 3. If the base has failed, reconstruction will be required and the base and surface thickness needs to be determined in accordance with Section 37-2, 37-3, 37-4, or 37-5.*

HMA MINIMUM OVERLAY THICKNESS
Figure 37-8C

37-8.06 HMA Overlay Thickness – Upgrading Structural Level

When it is proposed to place a HMA surface on an existing rigid or full depth HMA pavement, and upgrade the pavement to an 80,000 pound route, the thickness of the overlay may be determined by one of the following procedures. The District BLRS must approve any modifications or different

1. Evaluating Existing Material.

- a. AASHTO Guide for Design of Pavement Structure (1993). Part III, Chapter 5 provides the designer with overlay thickness design procedures to address structural deficiencies in various types of existing pavements (flexible and rigid bases
- b. Modified AASHTO. This method may be used when designing an overlay on existing flexible pavements or flexible base (see Section 37-8.07) or on existing rigid or composite pavements (see Section 37-8.08) by estimating the structural number value of the existing material and determining the IBV of the subgrade. The designer may then select the surface thickness and any additional base thickness required to satisfy the design structural number.

2. Asphalt Institute's "Asphalt Overlays for Highway and Street Rehabilitation" (MS-17) Deflection Analysis. Deflection is the amount of downward vertical movement of a pavement surface due to the application of a load. The magnitude of the pavement deflection is an indicator of the pavement's ability to withstand traffic loading. Research has established correlations between the wheel load, pavement deflections, and repetitions of the load.

Bituminous overlays on existing flexible pavements/bases may be designed by deflection analysis in accordance with the following procedure:

- a. Take an appropriate number of deflection readings on the existing roadway to be resurfaced. Obtain pavement deflections at a minimum rate of 20 per mile.
- b. Convert the deflection readings to spring (critical period) deflections. Conversions may be based on historical data, the Asphalt Institute's recommended procedure, or engineering judgment.
- c. Tabulate the deflections and compute a standard deviation.
- d. Deflections that fall outside the mean deflection plus 2 standard deviations should be set aside for special consideration. These areas will require additional treatment and/or additional structure.
- e. Compute a traffic factor for the project.
- f. Using the mean deflection plus 2 standard deviations, perform the Asphalt Institute's deflection based HMA overlay design procedures.

37-8.07 Modified AASHTO Design for Overlays on Existing Flexible Pavement/Bases

37-8.07(a) Application of Design Method

The modified AASHTO design procedures for flexible pavements enable the designer to determine the material types and thicknesses for the various layers of a flexible pavement that are required to carry a specified volume and composition of traffic for a designated period of time while retaining a serviceability level at or above a selected minimum value. Application of this design method involves the following steps:

1. Determine Traffic Factor. Use the following procedures to determine the traffic factor:
 - a. Determine the facility class (e.g., Class I, II, III, or IV) and the design period; see Sections 37-8.07(b) and 37-8.07(c).
 - b. Determine the actual structural design traffic as described in Section 37-8.07(d).
 - c. Based on the facility class, select the appropriate traffic factor equation from Figure 37-8E; see Section 37-8.07(e).
 - d. Calculate the actual traffic factor for use in design.
2. Determine the Immediate Bearing Value. Determine the Immediate Bearing Value of the roadbed soil; see Section 37-8.07(f).
3. Determine the Required Structural Number (SN_F). Determine the required flexible pavement structural number (SN_F) using the appropriate design nomograph for the facility class (i.e., Figure 37-8G for Class I facilities or Figure 37-8H for Class II, III, and IV facilities); see Section 37-8.07(g).
4. Determine the Existing Structural Number ($SN_{F,e}$). Determine the existing flexible pavement structural number ($SN_{F,e}$) using the appropriate coefficients from Figure 37-8I, the thicknesses of the existing pavement structure, and Equation 37-8.1 in Section 37-8.07(h).
5. Determine Structural Overlay Thickness. Determine the overlay thickness using equation 37-8.2 in Section 37-8.07(i).
6. Compare with Minimum Criteria. Compare the selected design with the minimum requirements presented in Figure 37-8J to ensure that the minimum design requirements have been met; see Section 37-8.07(j).

37-8.07(b) Classes of Roads and Streets

The class of the road or street for which the bituminous overlay design is being determined is dependent upon the structural design traffic. These road classifications are defined in Section 37-1.01.

37-8.07(c) Design Period

The design period DP is the length of time in years that the bituminous overlay is being designed to serve the structural design traffic. For bituminous overlays, the minimum DP allowed is 15 years for Class I, II, III, and IV roads and streets. However, designers are encouraged to determine thicknesses for both 15 year and 20 year DP's prior to selecting the final design thickness.

37-8.07(d) Structural Design Traffic

The structural design traffic is the estimated ADT for the year representing one-half of the design period. For example, when the design period is 20 years, the structural design traffic will be an estimate of the ADT projected to 10 years after the construction date.

The structural design traffic is estimated from current traffic count data obtained either by manual counts or from traffic maps published by IDOT. If PV, SU, and MU counts are not available for Class III and IV roads and streets, Figure 37-8D provides an estimate of counts that can be made from the component percentages of the total traffic.

Class of Road or Street	Percentage of Structural Design Traffic		
	PV (%)	SU (%)	MU (%)
III	88	7	5
IV	88	9	3

**PERCENTAGE OF STRUCTURAL DESIGN TRAFFIC
(Class III or IV)**

Figure 37-8D

37-8.07(e) Traffic Factors

For Class I, II, III, and IV roads and streets, the design TF for flexible pavements is determined from the 80,000 pound load limit formulas shown in Figure 37-8E. The formulas are based on the Statewide average distribution of vehicle types and axle loadings, which are directly applicable to most roads and streets.

BUREAU OF LOCAL ROADS & STREETS

Aug 2006

PAVEMENT DESIGN

37-8(7)

However, cases will arise in which the average formula should not be used (e.g., a highway where HCV's entering and leaving a site generally travel empty in one direction and fully loaded in the other). These cases should be referred to Central BLRS for special analysis. The local agency must provide Central BLRS with the structural design traffic, the DP, and traffic distribution by PV's, SU's, and MU's.

Class I Roads and Streets	
4 or 5 Lane Pavements (Rural and Urban)	$TF = DP \frac{(0.047 PV + 59.625 SU + 217.139 MU)}{1,000,000}$
6 or More Lane Pavements (Rural)	$TF = DP \frac{(0.029 PV + 53.000 SU + 193.012 MU)}{1,000,000}$
6 or More Lane Pavements (Urban)	$TF = DP \frac{(0.012 PV + 49.025 SU + 178.536 MU)}{1,000,000}$
One-way Streets and Pavements (Rural and Urban)	$TF = DP \frac{(0.073 PV + 66.25 SU + 241.265 MU)}{1,000,000}$
Class II Roads and Streets	
2 or 3 Lane Pavements	$TF = DP \frac{(0.073 PV + 56.03 SU + 192.72 MU)}{1,000,000}$
Class III Roads and Streets	
2 or 3 Lane Pavements	$TF = DP \frac{(0.073 PV + 54.57 SU + 192.175 MU)}{1,000,000}$
Class IV Roads and Streets	
2 Lane Pavement	$TF = DP \frac{(0.073 PV + 4.93 SU + 39.42 MU)}{1,000,000}$

**HMA OVERLAY ON FLEXIBLE PAVEMENT TRAFFIC FACTOR EQUATIONS
(80,000 Pound Load Limit)**

Figure 37-8E

37-8.07(f) Subgrade

The following material specifically relates to the modified AASHTO design methodology. The Immediate Bearing Value (IBV) plays a critical role in the modified AASHTO design methodology. However, other soil strength test procedures can be used provided that the test results can be directly correlated with those obtained by the IBV test procedure.

The IBV selected for use in design should represent a minimum value for the soil to be used. Preferably, testing should be performed on samples of the soils to be used in construction. It is

recommended that a soil survey be made prior to all construction; however, when test data are not available, use the values presented in Figure 37-8F.

See the Bureau of Materials and Physical Research's *Subgrade Stability Manual* for further guidance and information on obtaining field test data.

Soil Classification	IBV
A-1	20
A-2-4, A-2-5	15
A-2-6, A-2-7	12
A-3	10
A-4, A-5, A-6	3
A-7-5, A-7-6	2

SUGGESTED IBV VALUES FOR VARIOUS SOIL CLASSIFICATIONS

Figure 37-8F

37-8.07(g) Required Structural Number

Having calculated the traffic factor, only the IBV of the roadbed soil is needed to determine the required structural number of the flexible pavement. The flexible pavement required structural number (SN_F) is obtained by projecting a line through the traffic factor and the IBV on the appropriate design nomograph, either Figure 37-8G for Class I facilities or Figure 37-8H for Class II, III, and IV facilities.

37-8.07(h) Existing Structural Number

The existing structural number (SN_F), an abstract number related to the strength required of the total pavement structure, is the summation of the existing layer thicknesses multiplied by their corresponding strength coefficients from Figure 37-8I. Use the following equation to determine the existing structural number:

$$SN_{F,e} = a_1D_1 + a_2D_2 + a_3D_3 \quad \text{Equation 37-8.1}$$

Where:

- $SN_{F,e}$ = existing flexible pavement structural number
- a_1 , a_2 , and a_3 = coefficients of relative strength of the surface, base, and subbase materials, respectively
- D_1 , D_2 , and D_3 = thickness of the surface, base, and subbase layers, respectively, in

Granular Material, Type A, Crushed				0.11	0.09
Lime Stabilized Soil			100	0.10	0.08

Notes:

1. Marshall Stability (MS) index or equivalent.
2. Compressive strength (CS) in pounds per square inch (psi). For cement stabilized soils and granular materials, use the 7 day compressive strength that can be reasonably expected under field conditions. For lime stabilized soils, use the accelerated curing compressive strength at 120°F for 48 hours. For Pozzolanic, Type A, use the compressive strength after a 14 day curing period at 72°F.
3. Other approved materials of similar strengths may be substituted for those listed in this table.

COEFFICIENTS FOR MATERIAL IN HMA OVERLAY ON FLEXIBLE PAVEMENT/BASE
(Modified AASTHO Design)

Figure 37-8I

37-8.07(i) Overlay Thickness Design

In determining the structural overlay thickness, the existing structural number is subtracted from the required structural number of the pavement. This needed structural number is then divided by the resurfacing coefficient to determine the resurfacing thickness. Use the following equation to determine the required overlay thickness:

$$D_o = \frac{(SN_F - SN_{F,e})}{a_o} \quad \text{Equation 37-8.2}$$

Where: D_o = thickness of new HMA overlay, in
 SN_F = required flexible pavement structural number
 $SN_{F,e}$ = existing flexible pavement structural number
 a_o = coefficients of relative strength of the overlay material

Typical overlays using a 19.0 mm HMA binder course and a 9.5 mm or 12.5 mm HMA surface course the coefficient of relative strength (a_o) should be 0.36. If HMA surface course mixes are use the entire depth of the overlay, a_o may be increased to 0.40. Contact the Central Bureau of Local Roads and Streets for other special designs.

37-8.07(j) Minimum Thickness and Material Requirements

To ensure practical and adequate designs, the minimum design requirements presented in Figure 37-8J have been established. Final pavement thicknesses must comply with this table.

Structural Number (SN_F)		Minimum Thickness (in)	Minimum Material ^{1, 2}
From	To	Surface & Binder	Surface & Binder
< 2.50		2	Superpave with Low ESAL's
2.50	2.99	3	Superpave with Low ESAL's
3.00	3.49	3	Superpave (4% voids)
≥ 3.50		4	Superpave (4% voids)

Note:

1. Use Figure 37-4E to determine the appropriate PG Binder Grade.
2. Since polymer modified PG Binders may reduce the amount and rate of reflective cracks, polymer modified PG binders should be considered in all HMA overlaylifts.

MINIMUM THICKNESS AND MATERIAL REQUIREMENTS FOR HMA OVERLAYS ON FLEXIBLE PAVEMENT/BASE (Modified AASHTO Design)

Figure 37-8J

37-8.08 Modified AASHTO Design for Overlays on Existing Rigid/Composite Pavements

37-8.08(a) Application of Design Method

The design procedures for HMA overlay on rigid/composite pavements enable the designer to select: the thickness of bituminous surface needed to structurally rehabilitate an existing rigid or composite pavement. The resulting composite pavement will be capable of carrying a specified volume and composition of traffic for a designated period of time while retaining a serviceability level at or above a selected minimum value. The composite design method assumes that the existing rigid or composite pavement has reached the end of its design life and is in need of structural rehabilitation. If the existing pavement has not reached the end of its design life, as may be the case when a resurfacing is being designed in conjunction with a lane addition, higher strength coefficients than those discussed in Section 37-8.08(f) may be appropriate. Such cases should be referred to the Central BLRS. Application of the composite design method involves the following steps:

1. Determine Traffic Factor. Use the following procedures to determine the traffic factor:
 - a. Determine the facility class (e.g., Class I, II, III, or IV) and the design period; see Sections 37-8.08(b) and 37-8.08(c).
 - b. Determine the actual structural design traffic as described in Section 37-8.07(d).
 - c. Based on the facility class, select the appropriate traffic factor equation from Figure 37-8K; see Section 37-8.08(d).
 - d. Calculate the actual traffic factor for use in design.
2. Determine the Immediate Bearing Value. Determine the Immediate Bearing Value of the roadbed soil; see Section 37-8.07(f).
3. Determine the Structural Number (SN_c). Determine the required composite pavement structural number (SN_c) using the appropriate design nomograph for the facility class (i.e., Figure 37-8L for Class I facilities or Figure 37-8M for Class II, III, and IV facilities); see Section 37-8.08(e).
4. Determine Thickness. Select the appropriate equation from Section 37-8.08(f) as follows:
 - First Resurfacing: use Equation 37-8.3
 - Second Resurfacing: use Equation 37-8.4

Using the appropriate equation calculate the thickness of the HMA overlay. Round the thickness up to the nearest 0.25 in.

Note that these equations do not include provisions for a third resurfacing. Pavements that are in need of a third resurfacing for structural reasons often are badly deteriorated

and may no longer be functioning as a rigid pavement. Contact the Central BLRS for guidance in selecting the appropriate strength coefficients for such pavements.

5. Compare with Minimum Criteria. Compare the calculated thickness with the minimum requirements presented in Figure 37-8N; see Section 37-08(g). Use the larger of the values for design.

37-8.08(b) Classes of Roads and Streets

The class of the road or street for which the bituminous overlay design is being determined is dependent upon the structural design traffic. These road classifications are defined in Section 37-1.01.

37-8.08(c) Design Period

The design period DP is the length of time in years that the bituminous overlay is being designed to serve the structural design traffic. For bituminous overlays, the minimum DP allowed is 15 years for Class I, II, III, and IV roads and streets. However, designers are encouraged to determine thicknesses for both 15 year and 20 year DP's prior to selecting the final design thickness.

37-8.08(d) Traffic Factors

For Class I, II, III, and IV roads and streets, the design TF for rigid pavements is determined from the 80,000 pound load limit formulas shown in Figure 37-8K. The formulas are based on the Statewide average distribution of vehicle types and axle loadings, which are directly applicable to most roads and streets.

However, cases will arise in which the average formula should not be used (e.g., a highway where HCV's entering and leaving a site generally travel empty in one direction and fully loaded in the other). These cases should be referred to Central BLRS for special analysis. The local agency must provide Central BLRS with the structural design traffic, the DP, and traffic distribution by PV's, SU's, and MU's.

37-8.08(e) Composite Pavement Structural Number

Having calculated the traffic factor, only the IBV of the roadbed soil is needed to determine the required structural number of the composite pavement. The composite pavement required structural number (SN_C) is obtained by projecting a line through the traffic factor and the IBV on the appropriate design nomograph, either Figure 37-8L for Class I facilities or Figure 37-8M for Class II, III, and IV facilities.

(Modified AASHTO Design: Class II, III, and IV Facilities)

Figure 37-8M

37-8.08(f) Thickness Design Equations

The composite pavement structural number (SN_C), an abstract number related to the strength required of the total pavement structure, is a summation of layer thicknesses multiplied by their corresponding strength coefficients. Three design equations incorporate the composite pavement structural number as follows:

$$D_O = \frac{SN_C - 0.26D_C}{0.40} \quad \text{Equation 37-8.3}$$

$$D_O = \frac{SN_C - 0.25D_E - 0.17D_C}{0.40} \quad \text{Equation 37-8.4}$$

Where: SN_C = composite pavement structural number
 D_O = thickness of new HMA overlay (inches)
 D_C = equivalent thickness of existing PCC slab (inches)
 D_E = thickness of existing HMA surface (inches)

In the case of an existing jointed reinforced and non-reinforced PCC pavements of uniform thickness, the equivalent thickness of the PCC slab (D_C) is the actual slab thickness. For a CRC pavement, D_C is the slab thickness multiplied by 1.25.

37-8.08(g) Minimum Thickness and Material Requirements

To ensure practical and adequate designs, the minimum design requirements presented in Figure 37-8N have been established. Final pavement thicknesses must comply with this table.

Structural Number (SN_C)		Minimum Thickness (in)	Minimum Material
From	To	Surface & Binder	Surface & Binder
< 2.50		2	Superpave with Low ESAL's
2.50	2.99	3	Superpave with Low ESAL's
3.00	3.49	3	Superpave (4% voids)
≥ 3.50		4	Superpave (4% voids)

OVERLAYS ON RIGID/COMPOSITE PAVEMENT
(Modified AASHTO Design)**

Figure 37-8N

37-8.09 Design Example

* * * * *

Example 37-8.1

Given: Existing 73,280 pound Class I Urban One-way flexible pavement in District 6 with Slow Traffic.

The existing cross section is composed of -

- 3.0 in of Class I HMA surface,
- 12 in of Lime Stabilized Soil base, and
- 4 in of Granular Material, Type A, Crushed.

Design Traffic:

- ADT: 8900
- 94% PV (8366), 5% SU (445), 1% MU (89)

Subgrade Support Rating: Poor IBV = 4

Problem: Design an HMA overlay to upgrade the route to 80,000 pounds.

Solution:

1. This is a structural overlay; therefore, a pavement design procedure must be used. The designer may choose FWD testing, modified AASHTO, or other approved design methods. This example shows the modified AASHTO approach.
2. Using Figure 37-8E, determine the TF equation for a one-way Class I pavement for a design period of 15 years and 20 years.

One-way Streets and Pavements (Rural and Urban)

$$TF = DP \frac{((0.073 PV) + (66.250 SU) + (241.265 MU))}{1,000,000}$$

$$TF_{20} = 20 \left[\frac{(0.073 \times 8366) + (66.250 \times 445) + (241.265 \times 89)}{1,000,000} \right]$$

$$TF_{20} = 1.03$$

$$TF_{15} = 15 \left[\frac{(0.073 \times 8366) + (66.250 \times 445) + (241.265 \times 89)}{1,000,000} \right]$$

BUREAU OF LOCAL ROADS & STREETS
PAVEMENT DESIGN

37-8(20)

Aug 2006

$$TF_{15} = 0.77$$

4. Using Figure 37-8G and the given IBV of 4, the required flexible structural number (SN_F) is 3.9 for the 20-year DP and 3.8 for the 15-year DP.
5. Using Figure-8I and equation 37-8.1, determine the existing flexible structural number ($SN_{F,e}$):

$$SN_{F,e} = a_1D_1 + a_2D_2 + a_3D_3$$

$$SN_{F,e} = .30(3) + 0.09(12) + .11(4)$$

$$SN_{F,e} = 2.42$$

6. Using equation 37-8.2, determine the overlay thickness:

$$D_O = \frac{(SN_F - SN_{F,e})}{a_O}$$

$$D_{O,20} = \frac{(3.9 - 2.4)}{.36}$$

$$D_{O,15} = \frac{(3.8 - 2.4)}{.36}$$

$$D_{O,20} = 4.17$$

$$D_{O,15} = 3.88$$

These thicknesses should be rounded to the nearest 0.25 inches: $D_{O,20} = 4.25$ in and $D_{O,15} = 4.00$ in.

7. The minimum overlay thickness (D_O) for $SN_F \geq 3.50$ is 4.0 in (Figure 37-8J). Therefore, either the 15-year or 20-year DP will provide the minimum thickness. The designer should consider using the 20-year DP since this will only increase the pavement thickness by 0.25 inches. Based on Figure 37-4E, a PG 70-22 or SBS PG 70-22 binder may be used. Use of polymer modified binders may decrease the amount and rate of reflective cracks; therefore, the SBS PG 70-22 should be used.

Example 37-8.2

Given: Existing 73,280 pound Class I Urban One-way rigid pavement in District 6 with Slow Traffic.

The existing cross section is composed of -

- 8 in of jointed non-reinforced PCC pavement, and
- 4 in of Granular Material, Type A, Crushed.

Design Traffic:

- ADT: 8900
- 94% PV (8366), 5% SU (445), 1% MU (89)

Subgrade Support Rating: Poor IBV = 2

Problem: Design an HMA overlay to upgrade the route to 80,000 pounds.

Solution:

1. This is a structural overlay; therefore, a pavement design must be used. The designer may modified AASHTO or other approves design methods. This example shows the modified AASHTO approach.
2. Use Figure 37-8K and determine the TF equation for a one-way Class I pavement for a design period of 15 years and 20 years.

One-way Streets and Pavements (Rural and Urban)

$$TF = DP \frac{((0.073 PV) + (71.905 SU) + (348.210 MU))}{1,000,000}$$

$$TF_{20} = 20 \left[\frac{(0.073 \times 8366) + (71.905 \times 445) + (348.210 \times 89)}{1,000,000} \right]$$

$$TF_{20} = 1.27$$

$$TF_{15} = 15 \left[\frac{(0.073 \times 8366) + (71.905 \times 445) + (348.210 \times 89)}{1,000,000} \right]$$

$$TF_{15} = 0.95$$

3. Using Figure 37-8G and the given IBV of 2, the required flexible structural number (SN_c) is 3.3 for the 20-year DP and 3.2 for the 15-year DP.

BUREAU OF LOCAL ROADS & STREETS

37-8(22)

PAVEMENT DESIGN

Aug 2006

4. Using equation 37-8.3, determine the overlay thickness:

$$D_o = \frac{(SN_c - 0.26D_c)}{0.40}$$

$$D_{o,20} = \frac{(3.3 - 0.26(8))}{0.40}$$

$$D_{o,20} = 3.05$$

$$D_{o,15} = \frac{(3.2 - 0.26(8))}{0.40}$$

$$D_{o,15} = 2.80$$

These thicknesses should be rounded to the nearest 0.25 inches: $D_{o,20} = 3.25$ in and $D_{o,15} = 3.00$ in.

5. The minimum overlay thickness (D_o) for $3.00 \leq SN_F < 3.50$ is 3.0 in (Figure 37-8N). Therefore, either the 15-year or 20-year DP will provide the minimum thickness. The designer should consider using the 20-year DP since this will only increase the pavement thickness by 0.25 inches. Based on Figure 37-5G, a PG 70-22 or SBS PG 70-22 binder may be used. Use of polymer modified binders may decrease the amount and rate of reflective cracks; therefore, the SBS PG 70-22 should be used.

* * * * *

37-9 SURFACE TREATMENTS

A flexible pavement design procedure for bituminous surface treatments, A-2 and A-3, is not included in Chapter 37. Bituminous surface treatments, A-2 and A-3, may be constructed on roads and streets having an estimated ADT, upon completion, of 400 vehicles or less. The minimum thicknesses of base courses for these treatments are as follows:

- aggregate — 8 in,
- waterbound macadam — 8 in,
- Pozzolanitic — 6 in,
- bituminous stabilized — 6 in,
- cement stabilized — 6 in, and
- lime stabilized soil mixture — 8 in.

These minimum thicknesses for base courses are to be supplemented with subbase courses when necessary to compensate for poor subgrade soil conditions. The requirement for subbase may be determined on the basis of the applicable portions of Chapter 37 or some other acceptable method which has proven satisfactory in the past.

A-2 and A-3 bituminous surface treatments may not be placed on roads and streets having estimated ADT of over 400 vehicles upon completion.
